tory of such symptoms. These 1512 symptomless patients should be representative of apparently well women so far as gynecologic conditions are concerned, and the percentage of positive smears may be considered indicative of what might be expected among such women, barring chance errors.

\*Including specimens from clinics that did not submit thirty smears in any of the five periods

Eight positive smears were found, or 1 positive smear in 189 women without gynecologic symptoms. Of the 8 positive smears 5 were not confirmed by biopsy, although there is a possibility that some or even all of these patients had carcinoma in situ that will be confirmed at a later period. The true picture will probably lie somewhere between 1 in 189 and 1 in 500. Papanicolaou<sup>4</sup> has reported 2 symptomless cases of uterine cancer discovered by means of the vaginal smear among 500 women without gynecologic symptoms. Jones et al.<sup>5</sup> reported 3 cases of carcinoma discovered by the smear in patients without symp-

tom of carcinoma but no biopsies, and 27 furnished no evidence of uterine cancer. If only the patients with positive biopsies are considered, there would be 1 uterine cancer for every 16 women with gynecologic symptoms. The 27 smears diagnosed as positive but unconfirmed from the group of 1364

women with gynecologic symptoms combined with the 5 positive smears from those without a history or symptoms of gynecologic disorders make a total of 32 persons showing positive smears with no apparent uterine cancer at the time of the original smear.

A more detailed account of the smear diagnoses is presented in Table 2. The classifications are based on the diagnoses made on biopsy either at the time of smear or within a few days. On follow-up study it is probable that the classifications will be altered. The time required for final evaluation

\*Of the total of 3586 records collected 2876 were used, the remainder consisting of 454 specimens from patients with a history of uterine cancer, 153 specimens that were unsatisfactory and 123 specimens from patients with cancer of organs adjacent to the uterus which might have given false-positive smears.

†The proportions of positive smears were 1/189 in the total 1512 patients with no history or symptoms of gynecologic disorders (1/504 in the group in which the diagnosis was confirmed by biopsy) and 1/103 in the total 1364 patients with symptoms of gynecologic disorders (1/15.5 in the group in which the diagnosis was confirmed by biopsy). Many of these percentages are based on too small numbers to be significant.

toms suggestive of carcinoma from 182 patients examined in a gynecologic endocrine clinic.

Among the 1364 persons who presented gynecologic symptoms at the time of the smear 133 positive smears were obtained — an incidence of 1/10, 89 of these positive smears were confirmed by positive biopsies, 17 had clinical diagnoses of ques-

tion of carcinoma but no biopsies, and 27 furnished no evidence of uterine cancer. If only the patients with positive biopsies are considered, there would be 1 uterine cancer for every 16 women with gynecologic symptoms. The 27 smears diagnosed as positive but unconfirmed from the group of 1364

of a case will vary from a few days to three years. For example, a positive biopsy would confirm a positive smear, but in cases of carcinoma in situ, some time might elapse before a positive biopsy could be obtained to confirm a positive smear. Persons with negative smears, regardless of whether or not symptoms are present, are to be followed for

to all physicians in Massachusetts as another form of tumor diagnostic service. An advisory committee consisting of physicians particularly interested in this diagnostic technic was appointed to assist in planning the project. This committee consisted of Dr Thomas Almy,\* Dr John Fallon, Dr Reginald Fitz, Dr Joe V Meigs, Dr Maurice Fremont-Smith, Dr Edward G Huber,\* Dr Herbert L Lombard and Dr Shields Warren.

The following is an account of the procedure of this investigation and the initial results of two and a half years of study. Although the evaluation will not be completed for at least three years, the data at hand give some indication of what may be expected from the final analysis.

The collection and examination of the smears and the follow-up study of the patients were a joint undertaking of the Massachusetts Department of Public Health, the Tumor Diagnosis Laboratory and the state cancer clinics. All the eighteen Massachusetts cancer clinics took part in the program. Although the majority of the cases examined were from the two state cancer hospitals, Pondville Hospital and Westfield Sanatorium, several of the smaller clinics submitted smears from as high or even a higher proportion of their cases. At the time work began on this study, the vaginal smear was just beginning to be generally known, and it was therefore necessary to acquaint the staffs of the clinics with the method of obtaining secretions and preparation of the smears as well as with the purpose of the study. A prospectus of the study was sent to the physician in charge of each clinic. Personnel from the Tumor Diagnosis Laboratory studied the technic with Dr Papanicolaou and later, on request of the chief of each clinic, gave instructions regarding the making of smears. At the end of the first six months the test had been introduced in all but three of the eighteen state cancer clinics.

The necessary paraphernalia and record forms were supplied by the Tumor Diagnosis Laboratory and the Division of Cancer and Other Chronic Diseases. Pipettes were made at the laboratory and sold at cost to the clinics. Solution bottles for fixation of smears, mailing containers and requisition cards were supplied without charge. Forms for complete data on each case were sent to the follow-up workers of the clinics, who were responsible for filling them out. Each patient examined was given a card explaining that a new test had been performed and that she would be asked to return to the clinic later. A report on each smear was sent out from the laboratory to the clinic within two or three days of receipt of the smears.

The plan of study, which is still in progress, is as follows: obtaining a single smear from each person who attended the cancer clinics between January 1, 1945, and June 30, 1947, obtaining a follow-

up history and, whenever possible, a pelvic examination and a repeat smear at the end of three years after the original smear, and following for a longer period persons with unconfirmed positive smears. In a two-and-a-half-year period a single smear has been examined from each of 3586 women.

The smears were read by one technician. During the first part of the study each smear was examined for twenty minutes unless obvious carcinoma was found in a shorter time. As the number of smears increased, this rule could not be followed. No smear was examined for more than twenty minutes, but it was found that many smears could be adequately surveyed in much less time. Three forms of diagnoses were used: negative, biopsy and curettage indicated, and carcinoma, biopsy and curettage indicated. The smears with atypical, possibly malignant cells as well as many of the positive smears were reviewed by the pathologist. At the outset the pathologist and technician had had rather limited experience, but this lack was compensated for by the unfailing generosity of Dr G N Papanicolaou, who gave freely of his time on several occasions and so resolved many of the difficulties that would otherwise have been a serious hindrance. Also important was the help and encouragement derived from the monthly conferences with Dr Maurice Fremont-Smith, Mrs Ruth Graham and their co-workers at the Vincent Memorial Laboratory, Massachusetts General Hospital. We wish also to acknowledge our indebtedness to Dr J V Meigs, by whom we were first introduced to the method.

To determine how far the interest, familiarity with the method on the part of the staff of the clinics, and skill gained in diagnosis of smears would influence the study, the material is tabulated according to successive six-month periods during the two and a half years of study. The quality of the smears regarding proper spreading, fixation and so forth varied a good deal, especially in the first year. A definite improvement was seen in their preparation as time went on. Only smears that were entirely unreadable were classed as unsatisfactory. Table 1 shows a steady increase in the total number of specimens received during the first year and a half, and a gradual decrease during the second year. All the clinics alike showed the same trend.

Analysis of the records of the 3586 women examined gives the following information. There were 153 smears that were unsatisfactory for diagnosis, 434 from patients known to have a history of a uterine cancer, and 123 from patients with cancers of organs adjacent to the uterus. Among this last group positive smears might be present from extra-uterine sources. Omission of these three groups leaves records of 2876 patients available for study, of whom 1364 reported symptoms suggestive of gynecologic disorders, whereas 1512 gave no his-

\*Deceased

as a screening test, although more economical than other procedures available for detection of the earliest stages of cancer among large groups of apparently well persons, is not likely to bring to light many cases

The rather startling results obtained by the use of the vaginal smear in certain cases must be considered in relation to other factors such as the proved efficiency of the biopsy in disclosing early lesions and the possibility of curing lesions that, though still early, have given rise to symptoms. The early carcinomas with symptoms far outnumber the symptomless cases discovered (Table 4). Among 6265 patients examined by the vaginal smear only 8 symptomless carcinomas were found, but there were an estimated 39 "early" carcinomas that produced symptoms and were diagnosed by a positive biopsy as well as a positive smear. In only 5 cases of carcinoma was the initial biopsy negative while the smear was positive. The recent reports of carcinoma in situ by Fremont-Smith et al<sup>8</sup> and Isbell and his co-workers<sup>9</sup> indicate that most cases of carcinoma in situ present symptoms, although they are not always recognized as suggestive of cancer.

One of the important things the vaginal-smear technic has done has been to enlarge our understanding of symptoms and signs that should be considered as possible evidence of early carcinoma. It is not, we believe, generally appreciated what an impetus to the interest in early carcinoma has resulted from the studies on the application of the vaginal smear carried out by Dr Papanicolaou, Dr Meigs, Dr Fremont-Smith and their associates. In broadening the concept of the medical profession regarding early manifestations of carcinoma, these

workers have performed an unusual service in the field of education.

The technic is more likely to lower cancer mortality because it has made a large number of physicians aware of the insignificance of the signs and symptoms that may be associated with early carcinoma of the uterus than because of the number of early cases it discloses.

### SUMMARY

The present findings indicate that by the cytologic test for cancer it may be possible to find 1 case of uterine cancer among 200 to 500 women free from symptoms. The final evaluation of the technic as a screening test cannot be made until the results of the follow-up study are known three years hence.

found by different observers to be reliable in from 80 to 94 per cent of cases <sup>6</sup> The wide range of these findings probably depends on whether a single examination or multiple examinations were used for judging the accuracy of the smear method in the individual case The over-all error of interpretation has been reported as between 0 3 and 4 0 per cent in large series of cases (Table 3)

The method of computation of the percentage of error in general use has been to divide the number of mistakes by the total number of positive or negative cases to determine the false-positive or false-negative error For example, in Table 3 the 23 0 per cent false-negative smears means that among known cancer cases the smear diagnosis was correct in 77 and wrong in 23 per cent It

that only the smear with typical numerous tumor cells is accepted as evidence of carcinoma If this rule is followed, a positive diagnosis will not often be made, and one must rely on suggestive or descriptive reports

In this study smears that showed atypical but not distinctly malignant cells were reported under the heading of biopsy and curettage indicated The smears in this category, 261 in number, included those in which the evidence of a few cells was strongly in favor of carcinoma, and those in which the atypical forms present were not definitely suggestive of cancer but were yet unaccountable This is the most interesting group of the whole series inasmuch as early and premalignant lesions might be expected here if anywhere The answer to the

be a differential point except that it may also occur with incidental hypertension in patients who have brain tumor Judgment of the degree of arteriolar constriction may be an important factor, since ordinarily the most marked degree of vasoconstriction is found in severe hypertension with neuroretinitis

The findings from lumbar puncture offer guidance but not positive differentiation (Table 2) Increased spinal-fluid pressure may occur in severe hypertension either with or without papilledema The maximum elevation of cerebrospinal-fluid pressure (500 to 700 mm of water) occurred in the patients with brain tumor In the patients with malignant hypertension and papilledema the pressure never exceeded 450 mm of water It is evident that elevation of the cerebrospinal-fluid pressure is not a differential criterion The same statement may be made of the spinal-fluid protein, though from a comparison of these three groups of patients, the higher the spinal-

hypertension with papilledema (Grade IV, "malignant" hypertension) is encountered and that data from lumbar puncture alone, although helpful, are not positively diagnostic Since coincidence of

fluid protein the more likely is brain tumor (Table 3) The patients with hypertension may have a high protein, but it is more likely to be normal than that in patients with brain tumor A slightly elevated protein is occasionally encountered in severe hypertension without papilledema In only 2 of the patients with hypertension and choked disk (more than one diopter) was the nonprotein nitrogen over 40 mg per 100 cc initially In several cases the nonprotein nitrogen rose terminally As for the gold-

Study is not complete without a competent neurologic examination, skull plates, an electroencephalogram and sometimes air-injection studies

CASE REPORTS

CASE 1 In 1935 a 57-year-old woman entered the hospital with a history of known hypertension and exertional angina pectoris of 10 years' duration Failing memory had been noted for 5 months, and she had complained of severe frontal and left-sided headaches and had been stuporous for 9 days For the 12 hours prior to entry there had been vomiting and coma The blood pressure at entry was 180/100 Examination

## SEVERE HYPERTENSION WITH PAPILLEDEMA SIMULATING BRAIN TUMOR\*

## Differential Diagnosis and Treatment

ROBERT STERLING PALMER, M D,† ALBERT F NYSSENS, M D,‡ AND JAMES C WHITE, M D§

BOSTON

ESSENTIAL hypertension is a very common condition, and expanding intracranial lesions are common enough so that coexistence of the two may be anticipated. The symptoms (impairment of vision, headache, nausea, vomiting, convulsions, stupor, unconsciousness and coma), physical findings (papilledema and localizing signs) and spinal-fluid alterations (increased pressure and elevated protein) may occur both in severe hypertension and in brain tumor. Increased intracranial pressure associated with a slowly expanding intracranial lesion is not accompanied by a significant increase in the blood pressure. The presence of an acutely expanding intracranial lesion (from trauma or hemorrhage), which may cause an elevation of the blood pressure, is usually apparent. The differential diagnosis, therefore, is not a mutually exclusive one. The choice is between the severe form of hypertension with papilledema (Grade IV or malignant hypertension) and brain tumor with coexisting hypertension. Actually, in our experience the presence of brain tumor often requires consideration in patients with severe hypertension. Sometimes the suspicion of brain tumor remains in such patients, the possibility persisting in spite of appropriate and detailed investigation. Rarely, brain tumor in association with hypertension has mistakenly been considered severe hypertension with papilledema, and conversely exploratory craniotomy has sometimes been performed because an expanding intracranial lesion could not be excluded positively.

Because of the similarity in symptoms and signs between these two conditions and because patients have been encountered in whom essential hypertension and brain tumor coexisted, we have compared the symptoms, signs and spinal-fluid findings in 30 patients with severe hypertension and papilledema, in 25 patients with proved brain tumor and in 15 patients with severe hypertension but without papilledema. We wish to clarify this important problem.

## DIFFERENTIAL DIAGNOSIS

From a review of our data, striking similarities are apparent. In differentiating severe hypertension

with papilledema and expanding intracranial lesions with coexisting hypertension, the following observations are pertinent.

Severe hypertension with papilledema (Grade IV or "malignant") is most frequent under the age of fifty. Brain tumor is widely distributed at all ages. Severe hypertension without papilledema (Grade III) occurs most frequently at middle life and after, and is a little more common in women than in men. Grade IV or malignant hypertension is more common in men.

Headache appears to be actually more frequent and possibly more severe in the hypertensive cases. Symptoms referable to the heart are naturally more common in patients with hypertension, but would be expected equally in patients with brain tumor and coexisting hypertension. Cerebrovascular accidents are likely to be sudden and progress rapidly either toward improvement or to death, whereas the neurologic changes associated with brain tumor are more likely to be slowly and steadily progressive with or without episodic exacerbations. (*This difference in the course of the symptoms is, as a rule, one of the most important differential points*.) Our patients with hypertension and papilledema were taken for study as they appeared and were not selected because of hypertensive crises or hypertensive encephalopathy. It so happens that only 1 of this series of 30 patients had convulsions and unconsciousness. When hypertensive encephalopathy occurs there may be coma or stupor, with or without convulsions that may be general or unilateral, and with or without paresis. These crises may result in death or in recovery without residual symptoms. In brain tumor the neurologic changes are persistent and progressive. In the 25 patients with brain tumor convulsions occurred in 9, and unconsciousness in 12.

In the appearance of the fundi the character and degree of papilledema, the presence of atrophy and the finding of hemorrhages are not positively differential (Table 1). In one patient with brain tumor and without coexisting hypertension, exudate was found by a competent ophthalmologist. On the other hand, papilledema alone without hemorrhage or exudate occurred in 4 of the patients with hypertension. Unilateral choking with optic atrophy on the opposite side was found in 1 case of malignant hypertension, brain tumor being excluded by autopsy.

Of the 10 patients with hypertension and choked disks, the elevation was recorded as "several diop-

§Assistant professor of surgery, Harvard Medical School, chief Neurosurgical Service, Massachusetts General Hospital.

evidence of intracranial pressure appeared positive enough to warrant exploration. Craniotomy was done in 2 cases, and the author refers to similar experiences of others. The French school stress this similarity between severe hypertension with papilledema and space-taking intracranial lesions by referring to it as pseudotumoral hypertension<sup>4-8</sup>. From the cases cited the need for combined medical and neurologic study of these problems is obvious. With increasing use of air studies in the preoperative workup of cases in which brain tumor is suspected, which today is the custom in most clinics, errors of the sort reported are not likely to occur. We believe that this procedure should be routine in doubtful cases, especially when convulsive seizures or localizing neurologic signs are present.

#### PROGNOSIS, MORTALITY AND EFFICACY OF SYMPATHECTOMY

The outcome in these 30 cases of the severe form of hypertension justifies the ominous significance usually ascribed to the combination of hypertension and papilledema. The status of 2 patients is not known. Of the remaining 28 patients 3 are known to be alive nine to ten years after hospital study. Of the others 1 survived seven years, and 5 others survived between one and two years after hospital observation. The rest were dead in less than a year.

Four were postoperative deaths: 3 after dorsal sympathectomy and 1 after right nephrectomy for pyonephrosis, actually from bilateral adrenal hemorrhage. Three patients died with cerebral accidents. Congestive heart failure was the chief cause of death in 1 case, a contributory cause of death with uremia in 2 and was associated with cerebral accident in another. Uremia was a cause of death in 8 patients. One patient with adrenal paraganglioma died in a paroxysm of hypertension. One died a respiratory death evidently from a pressure cone, spinal puncture had not been done within two months. Seven patients died away from the hospital, the precise cause being undetermined.

Nine of the patients who died were autopsied, and in 7 of these the brain was examined. Aside from varying degrees of arterial and arteriolar disease, hemorrhage was present in 1 case, infarction in 3, a definite pressure cone in 2 and a questionable pressure cone in a third. In 1 the ventricles of the brain were enlarged to one and a half times their normal size. Hypertrophy of the heart was found in 8 cases, but the heart of the patient who died in a paroxysm of hypertension due to a paraganglioma was not enlarged. Malignant vascular nephritis was diagnosed pathologically in 3 cases and was questioned in 1. Chronic vascular nephritis was diagnosed in 3 cases. Only slight intimal thickening of the renal arterioles was found in the remaining kidney of the patient who died after nephrectomy. The kidneys of the patient with the adrenal paraganglioma were normal.

In this series of 30 patients with hypertension and papilledema, dorsal sympathectomy was performed in 15, and dorsolumbar sympathectomy in 1. Two of these died soon after operation. These deaths were ascribed to the advanced stage of the disease when the patients were operated upon. The third operative death was due to bilateral pneumothorax. Of the remaining 12 in whom dorsal sympathectomy was performed, 6 patients died within a year, and 3 within two years. One survived seven years after operation. Two patients are living ten years after dorsal sympathectomy. In 1 of these the blood pressure was unchanged, but the papilledema of two or three diopters entirely cleared up. In the other, eye grounds and vision became almost normal, but extensive peripheral vascular disease had developed. Another patient, one of the first to have dorsolumbar sympathectomy, is alive nine years after operation, but her precise condition is unknown.

#### DISCUSSION

Is papilledema of whatever degree, even though of less than measurable elevation, an infallible sign of the severe rapidly progressive form of hypertension? The uniformly fatal outcome in this group, except for 4 cases in which sympathectomy was performed, whether the papilledema was more or less than one diopter, certainly suggests that these patients have something in common that is of ominous significance. The foremost sign of this we believe, is edema of the optic disks. When we refer to malignant hypertension clinically, we mean the patients usually under fifty years of age who, with or without a previous known hypertension of milder degree, present severe symptoms of recent onset, commonly with intractable headache and failure of vision, who have a very high diastolic blood pressure and papilledema, and most of whom pursue a rapidly progressive clinical course to death within two years. This does not mean that in every case a pathological diagnosis of malignant nephrosclerosis (necrotizing arteriolitis) will be made at autopsy.

The possibility remains that all the patients with the diagnosis of malignant hypertension do not necessarily have an extremely poor prognosis. Mistakes may be made in patients with severe arteriolar sclerosis with extensive hemorrhages and exudate and in certain patients with marked vasospasm when the accompanying edema may not be so serious. In 1 of the patients surviving ten years after dorsal sympathectomy the presence of pathologic blurring or edema of the disks was somewhat questionable and, if present, may have been due to extensive vasoconstriction, hemorrhages and exudates. The acute onset, severity and apparent rapid progression of his disease indicated malignant hypertension. Individual cases of remission<sup>9</sup> and even prolonged survival<sup>10</sup> after a clinical diagnosis of malignant hypertension are on record, but these are considered exceedingly rare. The correctness

of the fundi showed papilledema of 3 or 4 diopters bilaterally, narrowing and tortuosity of the arterioles, hemorrhages but no exudate. There were no localizing neurologic signs, though the family thought the patient's actions had been peculiar, talk had been senseless, and there may have been drooping of the left eyelid. No difference in the size of the pupils was noted. An attack of severe substernal pain had occurred on the day of admission. Lumbar puncture showed an initial pressure equivalent to 350 mm of water and a total protein of 34 mg per 100 cc. The nonprotein nitrogen was 41 mg per 100 cc. The diagnoses were severe hypertension, with hypertensive encephalopathy and neuroretinitis, and hypertensive and arteriosclerotic heart disease with angina pectoris. Lumbar puncture was performed twice, with apparent improvement in the clinical condition. In the course of a few days rales appeared at the bases. The temperature rose to 104°F, the patient died. At autopsy, an unsuspected glioblastoma multiforme in the left frontal lobe was found, with signs of increased intracranial pressure (flattening of the convolutions), wet lungs, a slightly enlarged heart and coronary sclerosis with healed myocardial infarction.

This patient was rather old to be typical of severe hypertension with neuroretinitis. Her blood pressure, especially the diastolic, was too low to be typical. Concentration on the obvious and severe vascular disease, including disease of the retinal arterioles and the hypertension, and failure to evaluate properly the history and clinical findings misled the observers in this case. Known antecedent severe vascular disease and the recent cerebral symptoms were wrongly taken to be cause and effect. Lumbar puncture was a hazardous and ill considered procedure. This maneuver should not be done in patients with increased intracranial pressure before the needed information to be obtained has been balanced against the risk of inducing a pressure cone.

**CASE 2** A 63-year-old housewife had had variable hypertension for 1 year and 7 months and complained of unsteadiness and of soreness in the neck since a fall 6 months before admission. She stated that her eyes did not respond to her wishes. She was troubled by weakness of the arms and finally by numbness of the right side of the face and tongue with increasing deafness and tinnitus on the right. Blurring of the optic disks was found. Her blood pressure was as high as 200/125 when she was ambulatory and as low as 130/78 at rest. Lumbar puncture revealed an initial pressure equivalent to 150 mm of water, a total protein of 80 mg per 100 cc and a negative spinal-fluid Wassermann test. On exploratory craniotomy an acoustic neuroma in the right cerebellar pontine angle was found and removed. A year later she was known to be alive though still having some difficulty in walking.

The variable though at times very high blood pressure was incidental to the brain tumor, which, in this case, was obvious from the typical history of steadily progressive neurologic change.

**CASE 3** A 45-year-old woman had had hypertension (a blood pressure of 190/130) for 1 year and 3 months and constant headaches of 10 years' duration. On entry to the hospital in 1938 she complained of poor vision in the left eye and intermittent diplopia of 9 months' duration. A few days before admission there had been transient numbness of the lower lip and tongue and left lower arm. Her father and one brother had died suddenly at 65 and 47 years of age respectively. Bilateral choked disks were found (4 diopters on the left and 1 diopter on the right). The retinal arterioles were markedly attenuated. There were no exudates or hemorrhages. Examination of the urine was negative. Renal function was normal. On lumbar puncture the initial pressure was equivalent to 330 mm of water. The spinal-fluid protein was

29 mg per 100 cc. The spinal-fluid Wassermann reaction was negative, as were blood Wassermann and Hinton tests. X-ray films of the skull showed a grossly abnormal sella. A ventriculogram demonstrated both lateral and third ventricles to be displaced to the right. A left temporoparietal craniotomy revealed the brain under moderately increased pressure. The tumor proved to be an aneurysm of the internal carotid artery. Nothing could be done, and the wound was closed.

The gradually enlarging aneurysm in this case may have been primarily responsible for the recent symptoms and the increased intracranial pressure. Nevertheless, it was not possible to exclude with certainty the severe form of hypertension with papilledema. In support of this diagnosis were the headaches and poor vision since the age of thirteen, a known duration of hypertension of one year and three months with a very high diastolic pressure, marked attenuation of the fundus arterioles and age well within the usual range of severe hypertension with papilledema. In favor of a slowly developing intracranial tumor were the constant left-sided headache for several years, progressive failure of vision more marked on the left for several weeks, deformity of the sella and displacement of the lateral and third ventricles to the right.

With the recent increase in interest in and knowledge of intracranial aneurysm the disturbances in ocular movement and trigeminal hypesthesia, together with deformity of the sella, should have suggested the correct diagnosis. Precise interpretation is difficult, but we suspect that this patient may be an example of the coexistence of the severe form of hypertension with papilledema and an expanding intracranial lesion. It is reasonable to suppose that the very severe hypertension hastened the expansion of the aneurysm of the internal carotid artery.

Other observers have found this differential diagnosis interesting and at times difficult, as Cushing and Bordley<sup>1</sup> did forty years ago. Abbott et al.<sup>2</sup> report the case of a female patient aged forty-eight, who had hypertension and complained of weakness of the left hand for several years and who for two years had experienced convulsive seizures with residual paresis of the left arm and leg. In this case there was no papilledema, but the persistent localizing signs and the seizures should have suggested neoplasm with coexisting hypertension. Nevertheless, the patient was treated for the hypertension for over a year. The treatment included bilateral partial adrenalectomy after which there was apparent improvement in the blood-pressure level. Continued convulsive seizures and the persistent localizing signs finally led to skull plates, which showed bony change in the central region. At craniotomy a 150-gm meningioma was removed.

Grant<sup>3</sup> reports 5 cases seen in the course of two years diagnosed as suspected brain tumor because of choked disks, headache and suggestive neurologic signs. Before renal vascular disease was conclusively demonstrated, the neurologic symptoms and

that in certain selected cases in the hands of a competent surgeon, cerebral decompression may be justified in the presence of advanced visual failure. Dereux<sup>17</sup> advocates this procedure in the face of positive evidence of increased cerebrospinal-fluid pressure, progressive symptoms and ineffectiveness of medical measures.

On review of our own experience in the treatment of the hypertensive syndrome of increased intracranial pressure, both medical and surgical, and some of the reported surgical experiences of others, we conclude that cerebral decompression alone is rarely justified. Our reasons are as follows:

Craniotomy is a radical and dangerous procedure that by itself as a rule offers only doubtful and temporary relief in the rapidly progressive course of an almost always rapidly fatal disease.

Venesection drainage of the spinal fluid by lumbar puncture (with caution and only when an intracranial neoplasm has been excluded), hypertonic intravenous infusions and free use of intramuscular or intravenous magnesium sulfate are as often followed by as much relief, or recovery occurs spontaneously.

If improvement does not follow medical treatment, we think that irreversible pathologic change, thrombosis with infarction or hemorrhage of greater or lesser degree — or a combination of all three — is very likely. Craniotomy in this situation in the present state of knowledge and technic is not justified.

Kempner<sup>18</sup> has reported 33 patients "with papilledema, hemorrhage or exudate" who followed the rice diet for a period of at least eight weeks. In 21 cases "the retinopathy improved greatly or even cleared up entirely under the rice regime." The retinal photographs taken before and after treatment leave no doubt about the extraordinary improvement. The Selyes<sup>19</sup> are encouraged by the favorable results in malignant hypertension that follow the long-continued use of a low-sodium, low-protein, low-fat diet with high carbohydrate and large doses of ammonium chloride. Our experience with these regimes is not yet extensive enough for us to comment authoritatively. To date, the only patients with severe hypertension and papilledema whom we have seen definitely helped for considerable periods have been those submitted to sympathectomy. Final judgment of efficacy between the various surgical technics and medical regimes will depend upon the survival time of patients who conform to the clinical criteria for the diagnosis of malignant or Grade IV hypertension.

## SUMMARY

The similarity in symptoms, physical signs and spinal-fluid findings between severe hypertension with papilledema and expanding intracranial lesions is pointed out. A comparison is made of observations in 30 patients with severe hypertension and papilledema, in 25 patients with expanding intracranial lesions and in 15 patients with severe hypertension without papilledema.

The differential diagnosis between severe hypertension with papilledema and an expanding intracranial lesion with coincident hypertension is discussed and illustrated by a report of 3 cases. The most important differential characteristic is the slow, steady progression of neurologic localizing signs in brain tumor. Proper evaluation depends upon expert neurologic examination and sometimes upon supplementary pneumograms.

In our hands extensive sympathectomy has thus far been the measure that has relieved symptoms, reduced the papilledema and stayed the rapid progress to a fatal outcome that is almost uniform in patients with malignant hypertension. It is suggested that denervation of the splanchnic bed abolishes or minimizes the orthostatic pressor responses and thus protects the cerebral circulation.

of diagnosis and prognosis is indicated by the fatal outcome in 90 per cent of cases so diagnosed in two years. The efficacy of sympathectomy may be judged by the survival time of patients in whom malignant hypertension was diagnosed clinically who have been sympathectomized, as compared with those not so treated.

Keith, Wagener and Barker<sup>11</sup> reported 146 cases of malignant or Grade VI hypertension, of whom 79 per cent were dead in one year, 88 per cent in two years, 94 per cent in three years, 98 per cent in four years, and 99 per cent in five years. Our experience to date with the medical management of malignant hypertension is in accord.<sup>12</sup> The survival for seven to ten years of 3 out of 15 of our patients in whom dorsal sympathectomy was performed has been noted. Peet and Isberg<sup>13</sup> reported 21 patients (19 per cent) of 112 with malignant hypertension alive five to eleven years after dorsal sympathectomy. It was noted above that 1 of the first patients to have dorsolumbar sympathectomy is living nine years after operation, and it has been reported elsewhere that 5 of 11 patients with malignant hypertension were living three to five years after dorsolumbar sympathectomy.<sup>14</sup> Hammarström,<sup>15</sup> in reporting his experience with 101 hypertensive patients sympathectomized in the past five and a half years, states that of 17 patients with malignant hypertension sympathectomized, the median and mean length of life is definitely greater than that in the control material of Keith and Wagener.<sup>9</sup>

It is admitted that an exceptional case in which sympathectomy was performed may have erroneously been diagnosed as malignant hypertension, and that the patient may therefore have survived longer. It is also possible that the severity of the disease varies in patients who exhibit the clinical features of malignant hypertension, those with less severe disease surviving longer whether or not sympathectomized. Nevertheless, the mortality bears out the diagnosis and prognosis uniformly in the unoperated cases, and the operated cases exhibit the same clinical features. The important fact is that these clinical features are changed in a number of the operated patients. When successful, operation relieves the intractable headache, the papilledema disappears, and the rapid, intense course of the disease is slowed.

That the changes in advanced malignant hypertension may be reversed by sympathectomy is illustrated by the following case report.

A 35-year-old Navy officer, who had been working in the Radiation Laboratory at Massachusetts Institute of Technology, had complained of unusual fatigue for 6 months and headaches for 3 months, followed by blurring of vision and nocturia of 1 month's duration. Ten days prior to admission to the United States Naval Hospital in Chelsea he had suffered a series of convulsions, with amnesia, and had fallen out of bed injuring his forehead. On May 31, 1943, his fundi showed severe papilledema (5 diopters), with much exudate and scars of old hemorrhage. His heart was of normal size, but an electrocardiogram showed hypertensive changes. Neurologic

examination was negative. The urine gave a + test for albumin and contained a maximal concentration to a specific gravity of 1.021, the nonprotein nitrogen was 34.5 mg per 100 cc. An intravenous pyelogram was normal, and phenol sulfonephthalein excretion was satisfactory. Events are best recorded in chronologic order, as follows.

On May 19 the patient had convulsions. The cerebrospinal-fluid pressure was equivalent to 390 mm of water, and the protein was 20 mg per 100 cc.

Two days later the blood-pressure readings were 200/130 (recumbent), 190/140 (sitting) and 200/150 (standing). When the arm was immersed in ice water the blood pressure rose to 300/180.

On June 4, when the patient had had recurrent convulsions for the past 2 days, the fundi showed many recent hemorrhages.

On June 7, thoracolumbar sympathectomy (ninth thoracic to first lumbar segment) was performed by one of us (J.C.W.).

On June 15 the patient complained of more blurring of vision. Vertigo and headache were so intense that he could not get up. The blood pressure was 200/120.

On June 22 left thoracolumbar sympathectomy (eighth thoracic to second lumbar segment) was performed by one of us (J.C.W.). The blood pressure fell to 78/40.

On July 2 the blood pressure was 150/90. The patient noted improvement of vision. His headaches had disappeared, and he was no longer dizzy. He was out of bed and comfortable.

On July 8 the blood-pressure readings were 146/90 (recumbent), 136/90 (sitting) and 130/80 (standing). The cerebrospinal-fluid pressure was equivalent to 220 mm of water.

On August 14 there was remarkable improvement. The patient felt well and was swimming and skipping rope. He was discharged from the hospital on sick leave.

On December 21 the papilledema was gone, and the retinal exudates and hemorrhages had cleared. Vision had returned to normal, but the patient still tired easily and complained of occasional headaches. He had returned to work, and gave the interesting story of how, prior to his cerebral crisis, he had been working on an important problem in radar electronics. He had entirely lost track of this work, but after returning to his desk had soon picked up these ideas from his previous notes.

On August 1, 1944, he was working hard but tired easily. The blood pressure was 168/118, the heart was not enlarged. The urine was normal and the nonprotein nitrogen was 36 mg per 100 cc. The fundi were normal except for narrowed arteries with arteriovenous nicking.

On May 6, 1947 (4 years after sympathectomy), the patient was reviewed by Dr. K. A. Evelyn at the Hypertension Laboratory of the Massachusetts General Hospital. He was then an insurance salesman and doing regular work with only the complaints of slight fatigability and occasional mild headaches. Examination of the fundi revealed normal disks and a few residual scars of the old hemorrhages. There were moderate changes in the caliber of the retinal arteries, slight arteriovenous compression and barely noticeable broadening of the light reflex. An electrocardiogram showed only minimal hypertensive changes. The blood-pressure readings were 170/120 (recumbent), 160/110 (sitting) and 150/115 (standing). The rise on cold-pressor test was to 200/140 as against the preoperative rise to 300/180.

It is evident that the severe cerebral and retinal changes in this case of malignant hypertension were reversed and have remained controlled for four years. Although the patient has had a partial re-elevation of blood pressure to a more moderate hypertensive level and has mild residual symptoms, he has been able to lead a moderately active life and to earn his living.

Direct surgical relief of the hypertensive syndrome of increased intracranial pressure by decompression was suggested by Cushing and Bordley<sup>1</sup> in 1908. Grant<sup>3</sup> performed cerebral decompression in 2 patients and referred to similar experiences of others. Shelburne, Blaine and O'Hare<sup>16</sup> suggested

week. After discharge she attended irregularly for injections, and hence received an average of only one each month for the next year. Because of failure to reach normal blood values she was started on 50 mg of folic acid orally daily on September 9, 1947, and she continued to take this amount until the end of the year. At about Christmas time she developed some numbness and stiffness of the hands, together with difficulty in their use for finer motions. This lasted 4 or 5 weeks and then disappeared completely. From this time she took folic acid irregularly, sometimes averaging one dose of 50 mg every other day, but at other times omitting therapy for periods up to 1 week when her supply of medicine ran out.

Apart from some throbbing in the upper part of the chest she felt well until 1 week before entering the hospital. At that time, while walking in the street, she suddenly experienced a sensation of pressure about the upper abdomen as if she were wearing an elastic girdle, and at the same time her gait became unsteady. These symptoms persisted with some fluctuation in severity. Her legs felt numb from the knees down, and she had to be helped to the hospital by two friends because of the difficulty in walking.

Physical examination showed a pale, well nourished woman with normal findings except on neurologic examination, which revealed gross ataxia with positive Romberg's sign and defective position sense and pinprick perception in the toes. There was absence of vibratory sensation in the lower extremities.

Movements of the ankle, the knees and the fingers. Vibration sense, as tested with a heavy tuning fork (128 double vibrations), was slightly diminished in the middle and index fingers of both hands, absent over the sacrum and spinous processes below the second lumbar segment and only faintly perceived with maximum vibration applied to the iliac crests. Maximum vibration was not perceived in the patellas, tibias, ankles or feet.

On the 3rd hospital day, as a test of sensitivity, the patient was given a single intradermal injection of 0.01 cc. (0.15 U S P units injectable) of a pork liver extract in one forearm. This led to a severe and massive local reaction involving the entire volar aspect of the forearm and lasting 4 or 5 days. There was also a systemic reaction in the form of wheals on the opposite forearm and a choking sensation, relieved by 0.5 cc. of 1:1000 solution of adrenaline hydrochloride.

On the fifth hospital day treatment was started with injections of vitamin B<sub>12</sub>\* in doses of 5 microgm daily for a total of eight injections, the first being given intradermally and the subsequent ones intramuscularly. The intradermal injection was given in 0.2 cc of physiologic saline solution, producing a wheal that reached a maximum size of 2 cm in 30 minutes and subsided entirely in a few hours. No systemic symptoms followed the intradermal or the subsequent intramuscular injections of vitamin B<sub>12</sub>, each of which contained 5 microgm, an amount approximately forty-five times as

TABLE 1 (Continued)

DAY OF THERAPY	POSITION SENSE	PLANTAR REFLEXES		TENDON REFLEXES	NUMBNESS	
		RIGHT	LEFT		HANDS	FEET
1	Absent in toes	Extensor from outer border of foot	Poor flexor (equivocal) from outer border	Greatly increased	Present	Distal to both ankles
6	Absent in toes	Extensor	Flexor	Increased	Absent	Distal to both ankles
10	Absent in toes	Flexor	Flexor	Normal	None	In toes
13	Inaccurate for slight movements of toes only	Flexor	Flexor	Normal	None	In toes
19	Inaccurate for moderate and slight movements of toes	Flexor	Flexor	Increased	None	In toes
23	Inaccurate for very slight movements of toes only	Flexor	Flexor	Normal	None	In great toes only
60	Inaccurate for very slight movements of toes only	Flexor	Flexor	Normal	None	Very slight in right great toe only

The plantar responses were of flexor type. The day after entering the hospital she noticed numbness of the tips of the index and middle fingers, and examination demonstrated hypalgesia at these sites.

Examination of the blood disclosed a red-cell count of 1,920,000, with a hemoglobin of 6.5 gm per 100 cc. (42 per cent), a mean corpuscular volume of 104 cubic microns, a mean corpuscular hemoglobin concentration of 32 per cent and a mean corpuscular hemoglobin of 33 micromicrogm. The reticulocytes were 0.6 per cent, and the white-cell count was 2200.

The patient was placed on a diet free of meat, fish and eggs. Folic acid was discontinued, and no antianemic therapy was given for the first 4 days. On the 4th hospital day she was grossly ataxic in walking, requiring continued support and assistance. When she stood with the eyes open she swayed, and when the eyes were closed she fell backward within 10 seconds. There was no affection of vision, and the optic disks were normal. The hands were used clumsily, but there was no weakness. The tendon jerks in the upper limbs were all very brisk — the right more than the left. The lower limbs were ataxic in heel-shin tests but were not weak. The knee and ankle jerks were very brisk, and the left ankle jerk was more increased than the right. The right plantar response was extensor from the outer border of the foot, and flexor from the inner. Sensation to pinprick was diminished over the two distal phalanges of the fingers of both hands and distal to both ankles. No loss of sensation to cotton wool could be found in any part. The muscles were not tender. Sensation of position was absent in both great toes, but was present for gross

great as that contained in the 0.01 cc. of liver extract tested.

The reticulocytes began to rise on the 4th day of treatment and reached a peak of 16.0 per cent on the 6th day. By this time the patient felt well and displayed an excellent appetite. After 10 days of vitamin B<sub>12</sub> therapy the red-cell count and the hemoglobin had risen to 2,840,000 and 9.0 gm per 100 cc. (58 per cent), respectively.

Remarkable changes in the neurologic disorder were already evident by the 10th day of treatment. The recent numbness of the fingers and clumsiness in using them had vanished by the 4th day. On and after the 6th day of treatment an extensor plantar response was rarely obtained. By the 10th day the patient could walk without support, with only occasional unsteadiness, the tendon reflexes were of normal amplitude, and the plantar responses were both clearly flexor. By the 13th day mild vibration was appreciated in the right patella, and maximum vibration was perceived in the right tibia and left patella.

Beginning on the 9th day after the start of therapy, treatment with vitamin B<sub>12</sub> was discontinued for 7 days because of delay in obtaining a further supply of the material. After the 13th day there was a slight setback in the neurologic improvement, so that by the 19th day there was a reversion of neurologic signs to their status of the 6th and 10th days. This finding was reported by the neurologist without his knowledge of the lapse in treatment.

Treatment was reinstituted on the 16th day in doses of 5 microgm of vitamin B<sub>12</sub> intramuscularly three times a

EFFECTIVENESS OF VITAMIN B<sub>12</sub> IN COMBINED SYSTEM DISEASE\*

## Rapid Regression of Neurologic Manifestations and Absence of Allergic Reactions in a Patient Sensitive to Injectable Liver Extracts

LIONEL BERK, M D , P H D ,† DEREK DENNY-BROWN, M D ,‡ MAXWELL FINLAND, M D ,§ AND WILLIAM B CASTLE, M D ¶

BOSTON

IT IS well known that in patients with pernicious anemia, adequate therapy with desiccated stomach, whole liver and liver extracts for oral use, or with crude or refined liver extracts given by injection, will arrest the progress of combined system disease and may bring about a variable amount of recovery of nervous function, depending on the duration and severity of the process.<sup>1</sup> Since in many

A crystalline substance, vitamin B<sub>12</sub>, has recently been isolated from liver extracts<sup>2</sup> and found to produce hematologic remissions in pernicious anemia.<sup>3</sup> An unusual opportunity for testing the effectiveness of vitamin B<sub>12</sub> upon the neurologic disturbance of pernicious anemia presented itself in a patient who had developed acute combined system disease while receiving hemopoietically inadequate doses of

TABLE 1 Results of Vitamin B<sub>12</sub> Therapy\* in a Patient with Combined System Disease and Pernicious Anemia

DAY OF THERAPY	PINPRICK SENSATION		VIBRATION PERCEPTION	ATAXIA	ROMBERG'S SIGN
	FINGERS	FEET			
1	Impaired index and middle fingers	Impaired distal to ankles	Absent at toes ankles tibias patellas and below 2nd lumbar segment	+++	++
6	Normal	Impaired distal to ankles	Absent at toes ankles tibias patellas and below 2nd lumbar segment	+++	++
10	Normal	Impaired in toes	Present in right patella	+	+
13	Normal	Slightly impaired in toes	Present in 3rd lumbar segment, both patellas and right tibia	±	+
19	Normal	Impaired in toes	Absent in left patella both tibias and feet	±	+
23	Normal	Slightly impaired in great toes only	Present in both patellas and both tibias	±	+
60	Normal	Normal	Present in right internal malleolus	None	Negative

\*Therapy consisted of 5 microgm intramuscularly each day for eight days. Treatment was omitted from the ninth through the fifteenth day and resumed (in doses of 5 microgm three times a week) from the sixteenth day onward.

patients the neurologic and hematologic manifestations of pernicious anemia differ strikingly in degree, the possibility exists that these abnormalities are due to deficiency of two different substances, both of which are contained in the therapeutic agents listed above. The frequent development or relapse of neurologic lesions in spite of favorable hematologic response or maintained normal hematologic status in patients with pernicious anemia under treatment with synthetic pteroylglutamic acid,<sup>2</sup> presumably a single pure substance, lends additional support to the possibility that the neurologic and hematologic disorders arise from different deficiencies.

synthetic pteroylglutamic acid. The patient also had an acquired allergic sensitivity to injected liver extracts. It was of additional interest, therefore, to determine the relation of vitamin B<sub>12</sub> to this sensitivity.

## CASE REPORT

A 41-year-old mulatto woman entered the hospital on May 26, 1948, because of ataxia. She had been admitted to the hospital because of anemia 6, 4 and 2 years previously. Histamine-fast achlorhydria was demonstrated repeatedly, and at the first two admissions she showed adequate hematologic and clinical response to the injection of purified liver extracts. After she had received injections of liver extracts derived from pork for 9 months without discomfort, she experienced generalized urticaria and itching after each of two such injections. Relief followed a change of therapy to beef-liver extract. After receiving the latter for 10 months the patient began to react to this substance also. Positive skin tests to both pork and beef extracts were demonstrated, nine different commercial liver preparations being used. Consequently, on the third admission in September, 1946, she was treated intramuscularly with synthetic pteroylglutamic acid (folic acid) in doses of 10 mg daily for 10 days, again with typical hematologic and clinical responses. No neurologic changes were demonstrable at any of the three admissions. Before discharge from the hospital she received four doses of folic acid, 75 mg each intramuscularly at intervals of a

## CONDITIONED-REFLEX TREATMENT OF CHRONIC ALCOHOLISM

### Results Obtained in 2323 Net Cases from 3125 Admissions Over a Period of Ten and a Half Years

PAUL O'HOLLAREN, M D,\* AND FREDERICK LEMERE, M D†

SEATTLE, WASHINGTON

THE conditioned-reflex treatment of chronic alcoholism, as employed at the Shadel Sanitarium, consists of establishing an aversion to the sight, taste, smell and thought of all types of alcoholic beverages. This is accomplished by repeated conditioning seances, which may number four to eight before the desired aversion is established.

An individual seance consists of the administration of a nauseant drug, emetine, which, acting as the unconditioned stimulus, elicits an unconditioned reflex. Immediately before the onset of nausea a patient is given various types of alcoholic beverages (the conditioned stimulus). After the repetition of several such seances a conditioned-reflex aversion against all types of alcoholic beverages is developed, and the patient has a deep and lasting aversion to the sight, taste and smell of each. Details of technique have been published elsewhere.<sup>1-4</sup>

From the middle of 1935 to the end of 1945 there were 3125 admissions for the treatment of chronic alcoholism. These were unselected cases. No patient was refused treatment except for physical incapacity, psychotic tendencies or obvious insincerity. Patients treated subsequent to 1940 were offered a year's reinforcement program<sup>5</sup>—that is, the initial conditioned reflex was reinforced by periodic single conditioning seances for a year after treatment.

These 3125 cases represented people from all walks of life. Social status ranged from the very rich to the very poor—from the highly trained professional man to the former inmates of state institutions. Practically every type of labor, trade and profession was represented, indicating that alcoholism is no respecter of person, class or intelligence. The ages ranged from twenty to seventy-eight years. The vast majority of the patients, however, fell into the age group from thirty-five to fifty-five. Ninety-three per cent of the patients were men. Indications are, however, that the percentage of women will be higher in the future series. Types of personalities varied from the well adjusted business or professional man to the more severe type of psychoneurotic.

The treatment is a safe procedure if administered by properly trained personnel. There were only 3 deaths that might be associated with the treatment. Of these, one resulted from congestive heart failure, and 2 from coronary occlusion. Its wide applica-

bility is seen in the fact that only 32 patients, or approximately 1.100, were believed unfit physically to take the treatment. The only intellectual requirement was that the patient not be psychotic and that he be sincere in wanting to overcome his problem.

#### ESTABLISHMENT OF NET CASES

Of the 3125 patients admitted during this period, 304 did not complete treatment. Of these 135 refused to accept treatment after sobriety was established, 32 were refused treatment because of physical disabilities such as severe heart disease, advanced arteriosclerosis and perforating ulcer, 31 refused to complete treatment after it was begun, and 13 were refused treatment because of psychotic symptoms or obvious insincerity. The reason for not giving treatment to 86 patients was not shown on the hospital records. There were 7 deaths in this group, 4 were secondary to delirium tremens, and 3 were considered secondary to the treatment. Patients who could not be traced numbered 448. In 50 patients who died before the closing of this survey the cause of death was also classified as "unknown" even though they were sober at the time of death. This was necessary for statistical purposes because it could not be said that they would have remained sober until the close of the survey. There were, therefore, 2323 patients who were treated and whose status was definitely known at the closing date of the survey.

#### RESULTS

The tabulated data showing the percentage of abstinence among the net cases are presented in Figure 1. Continuous and complete abstinence from alcohol in any form, from the time of treatment until the closing date of the survey, was necessary for the patient to be classified as abstinent. Of the 2323 patients treated over the previous ten and a half years 1042, or 44.8 per cent, were found to be abstinent at the close of the survey in 1945. An additional 92 patients were retreated a short time after relapse and remained abstinent, giving an over-all figure of 48.8 per cent for the entire series.

A better understanding of the effects of time on the abstinence ratio can be had if the ten and a half years are divided into twenty-one periods of six months each as shown in Figure 1. From this it can be seen that about 85 per cent will remain abstinent for six months, about 70 per cent will remain abstinent for a year, 60 per cent will remain abstinent for

†Staff psychiatrist, Shadel Sanitarium.

week. By the 21st day further improvement was already appreciable. Vibration sense had been regained in both tibias, as well as in both patellas, and the tendon reflexes had returned to normal. By this time also hypalgesia had become difficult to demonstrate, position sense was remarkably accurate and the gait showed only a slight falter. From then on progress was slower. Sixty days after the beginning of treatment, the patient's gait was natural and she was able to stand with eyes closed without swaying. There was still slight numbness of the right great toe, but not elsewhere. The plantar responses were both clearly flexor, the tendon jerks were of normal amplitude, and there was doubt, if any, disorder of sensation to touch or pinprick. Sense of position was acute in all extremities except for appreciation of very small movements in the right great toe and small movements in the left great toe. Vibration was just appreciated over the internal malleolus on the right side and was readily perceived over both tibias and patellas. The neurologic findings are summarized in Table 1.

On the 24th day the red-cell count had reached 3,380,000, and the hemoglobin 10.2 gm per 100 cc (65 per cent).

### DISCUSSION

In view of the fact that marked anemia was present at the time of the development of the neurologic symptoms, it is difficult to decide whether the neurologic disturbance occurred as a natural event in the history of the disease or whether its development can be attributed to the previous synthetic pteroylglutamic acid therapy. Although the neurologic findings were entirely consistent with the presence of combined system disease, it is possible that the improvement may have been due simply to the cessation of folic acid therapy at the time of entry. Against such an explanation is the progression of the neurologic lesion during the first four days under observation and the rapid and extensive improvement following the initiation of vitamin B<sub>12</sub> therapy on the fifth hospital day. Especially significant is the slight setback during interruption of vitamin B<sub>12</sub> therapy with further recovery after its resumption.

These findings indicate that, as with previous stages in the purification of liver extract, the achievement of a crystalline derivative with intense hemopoietic activity has not diminished the ability of the material to arrest and in part to reverse recent neurologic manifestations of pernicious anemia.<sup>1,5</sup> The dramatic changes in this patient strongly suggest that a deficiency of vitamin B<sub>12</sub> is closely related to the natural origin of both the blood and the nervous changes. They should not be interpreted to

mean that vitamin B<sub>12</sub> was more effective than treatment with liver extract would have been.

It is evident that the neurologic lesion in this patient was in great part reversible, exemplifying the stage of "biochemical lesion" that precedes the structural degeneration of the spinal cord. The experience recorded above emphasizes the well known fact that spinal-cord symptoms of combined system disease constitute a medical emergency. The longer the lesion has existed, the more difficult it is to reverse.

The findings in this case also suggest that allergic sensitivity to liver extract is due not to sensitivity to the active principle itself but to other material in liver extracts, with species specificity, as demonstrated by Bauer and his co-workers.<sup>6</sup>

### SUMMARY AND CONCLUSIONS

In a patient with pernicious anemia in relapse and acute combined system disease that developed during irregular treatment with synthetic pteroylglutamic acid, a hematologic remission and rapid and marked improvement in the neurologic picture followed treatment with crystalline vitamin B<sub>12</sub>. The patient showed severe local and systemic sensitivity reactions to purified liver extracts derived from both pork and beef, but not to vitamin B<sub>12</sub>.

The findings in this patient suggest that vitamin B<sub>12</sub>, like the presently available injectable liver extracts, should prove effective against the neurologic as well as the hematologic manifestations of pernicious anemia. They also suggest that vitamin B<sub>12</sub> is not responsible for sensitivity reactions to liver extracts.

about 55 per cent will remain abstinent for three years, 40 per cent will remain abstinent for four years, 30 per cent will remain abstinent for seven years, and 25 per cent will remain abstinent up to ten and a half years or longer.

The treatment is of definite benefit both economically and from a social standpoint, even for patients who have relapsed. The relapsed patients remained abstinent for an average of slightly more than eleven months before resuming drinking.

The results obtained prove, beyond all reasonable doubt, the inherent value of this treatment. Adjunct forms of therapy have been used more extensively since this survey has ended. Their ultimate value, however, has as yet not been fully determined.

Factors such as age, occupational stability, marital unhappiness, nervousness, history of recurrent delirium tremens and financial indolence have a definite effect upon the prognosis, either favorable or unfavorable. Further studies of these influences may prove of value in determining the type and extent of treatment necessary in the individual case.

These patients closely represented a cross section of humanity from an occupational and social standard as well as personality types. The wealthy, the middle class, the poor and the gamut of all classifications of character types were amply represented.

It is hoped that the conditioned-reflex will be utilized more widely and combined with other forms of therapy in selected cases since it assists therapists by helping the patient remain abstinent while a program of personality and environmental adjustment is carried out.

## MEDICAL PROGRESS

### PREGNANCY TESTS\*

STANLEY L. ROBBINS, M D †

BOSTON

IT IS remarkable that a condition so essentially benign and self-limited as pregnancy, which must inevitably become obvious in the due course of time, has evoked so much interest in its early diagnosis. Despite the fact that in all but possible ectopic pregnancies no great need for speed in diagnosis truly exists, constant emphasis has been attached to the time required for the performance of a pregnancy test. As a result, although the first modern pregnancy test, the Aschheim-Zondek, which was described approximately twenty years ago, has never been surpassed for accuracy, new procedures have appeared each year, designed essentially to cut down the time required for a diagnosis. In addition, the practice of attaching the name of the investigator to each modification of an established test has created so many new tests that intimate knowledge of each is now virtually impossible for any one person. In general, however, the great variety of procedures fall either into one

of several well defined categories, such as biologic assays, chemical assays and skin tests, or into a heterogeneous group, which is composed of such procedures as white-cell counts, biopsy technics and others.

It is the purpose of this paper to review critically the historical development of present-day pregnancy tests and to discuss briefly tests that have gained acceptance by clinical trial as well as those that bear promise for the future. Accepted or new technics now in current use are discussed individually, their *modus operandi* being emphasized. It is perhaps well to state at the outset that no perfect pregnancy test exists and that it is certainly impossible to select any one of the existent procedures described below as best. However, in considering the advantages and disadvantages of each, it is hoped that the specific value of each technic will be better appreciated and its place in pregnancy diagnosis more clearly defined.

#### HISTORICAL REVIEW

From existing translations of Egyptian papyrus it is evident that tests for pregnancy were per-

\*From the Mallory Institute of Pathology, Boston City Hospital.

†Assistant professor of pathology, Boston University School of Medicine; instructor in pathology, Tufts College Medical School; instructor in pathology, Harvard Medical School; assistant pathologist, Mallory Institute of Pathology, Boston City Hospital.

two years, about 55 per cent will remain abstinent for three years, about 40 per cent will remain abstinent for four years, over 30 per cent will remain abstinent up to seven years, and about 25 per cent will remain abstinent up to ten and a half years or longer

While the data pertaining to the results obtained were being compiled a more comprehensive analysis

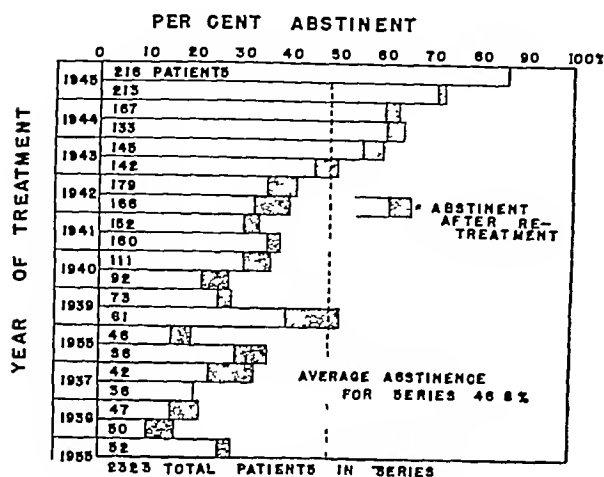

FIGURE 1. *Abstinence (Percentage) for Each Six-Month Period from the Middle of 1935 to the End of 1945*

The number of patients in each group is also shown. The stippled area represents an additional percentage obtained from 92 patients who remained abstinent as a result of retreatment shortly after relapse

of the patients in this series was carried out. A full analysis of these findings will be reported elsewhere.<sup>6</sup> Many salient factors influencing prognosis in the alcoholic patient were brought out by this analysis.

Such factors as marital happiness, occupational success, intelligence, financial security, interest in sobriety clubs, good co-operation and emotional stability were indicative of good prognosis, whereas marked nervousness, even when the patient was sober, a history of recurrent delirium tremens, instability about occupation, financial indolence and alcoholism under thirty years of age indicated a poorer although not a hopeless prognosis.

This group of patients is believed to be one of the largest reported from a single source in the United States. Except for varying amounts of field rehabilitation, conditioned-reflex therapy was the only treatment that these patients received for their alcoholism. In our opinion the gratifying results obtained definitely prove the inherent value of conditioned-reflex therapy in the treatment of this disease. Even in patients who relapsed it was definitely worth while from both an economic and a social standpoint. This is better demonstrated in Table 1.

For example, 94 patients remained totally abstinent for more than 30 months before they relapsed.

Three hundred and twenty-one remained totally abstinent from 6 to 30 months. An average period of 11.2 months of abstinence was obtained in this group of relapsed patients. A total of 9715 man months, or 809 man years, of total abstinence was accomplished among the relapsed patients. Many have since been retreated and are sober but are not included as successful cases.

Another advantage of the conditioned-reflex treatment is the easy manner in which it blends with adjuvant therapies. This is particularly true of psychotherapeutic approaches, such as an interview under pentothal narcosis.<sup>7</sup> In assisting the patient to remain abstinent while a program of environmental and personality adjustment is carried out, conditioning therapy renders a valuable assistance to the psychotherapist. Of significance in the analysis of the relapsed patients is the fact that 30 per cent of the patients admitted had apparently been in need of psychotherapy. This was determined in a study of the "reasons" for relapse among these cases.

Since the close of this survey approximately 2000 additional cases have been treated. Many of these patients have been and are being given adjuvant forms of therapy in addition to the conditioned

reflex. This includes pentothal narcoanalysis and psychotherapy, intensive physical and social rehabilitation and, in a very few selected depressed cases, shock therapy. It is hoped that this additional therapy and evaluation will improve the prognosis in the alcoholic patients as well as encourage the use of a more comprehensive therapeutic program elsewhere.

#### SUMMARY AND CONCLUSIONS

Statistical evaluation of 2323 net cases treated by conditioned-reflex methods over a period of ten and a half years and data concerning 3125 admissions are presented.

Eighty-five per cent of patients treated by this method will remain abstinent for six months or longer, 70 per cent will remain abstinent for a year, 60 per cent will remain abstinent for two years,

Frech,<sup>34</sup> Sheehan<sup>35</sup> and Hadley<sup>36</sup> have reported that the difficulty in reading the endpoint was considerable and, moreover, that the specificity of the reaction was open to grave doubt, positive reactions having been obtained by the simple addition of sugar to the urine

The colorimetric test of Schmulovitz and Wylie,<sup>37</sup> based on the detection of estrin in the urine, appears also to be of limited value, since according to Pincus<sup>38</sup> it is not reliable in early pregnancy when estrin titers are frequently low

Fairly recently a colorimetric test has been described by Guterman<sup>39</sup> It is based on the observation by Venning and Browne<sup>40</sup> that pregnanediol (an excretion product of the corpus luteum hormone) is excreted in the urine of pregnancy in increasing amounts throughout gestation Too little time has elapsed since the advent of this technique to permit adequate evaluation, however, several reports have appeared suggesting that its accuracy is below that of the Aschheim-Zondek test or its Friedman modification, and, moreover, false-positive tests may occur under conditions of delayed menstrual periods<sup>41, 42</sup> Notwithstanding these reports, this chemical test for pregnancy, free of the encumbrances of the use of animals and based on sound endocrinologic principles merits careful evaluation

Other techniques too numerous to mention have been devised for the laboratory diagnosis of pregnancy None of them have successfully stood the rigid test of clinical trial, and they have therefore never gained any universal acceptance For the sake of completeness alone, perhaps the following few merit mention Prostigmin has been administered in problems of delayed menstruation on the hypothesis that prostigmin "will induce menstruation in a nonpregnant woman and should no menstruation occur, the woman is invariably pregnant."<sup>43</sup> Several skin tests have been advocated, on the assumption that the reactions that develop will serve to differentiate pregnant women from nonpregnant women Placental extract,<sup>44</sup> colostrum<sup>45</sup> and antuitrin-S<sup>46</sup> are some of the most commonly used agents In the placental test the pregnant woman reacts more strongly to the antigen, and in the antuitrin-S and colostrum tests the reverse is true Although these last few tests receive sporadic attention in the literature, it is fairly well agreed that to date they are not totally reliable

From this historical review it is evident that great strides in the diagnosis of pregnancy have been made, however, a test for pregnancy that is 100 per cent accurate and capable of being performed in a test tube within a few minutes has yet to be found

#### FUNDAMENTAL PHYSIOLOGY

Basically all the common pregnancy tests, such as the Aschheim-Zondek, Friedman, rat hyperemia

and frog tests, consist of animal assay methods of detecting the high levels of hormone produced during pregnancy Hence, they rest upon two fundamental facts that during pregnancy there is an increase in either the production or the excretion of these hormones, and that these hormones produced by the human female will effect demonstrable changes in lower animals

Present knowledge of the endocrinology of pregnancy has undergone many changes and much

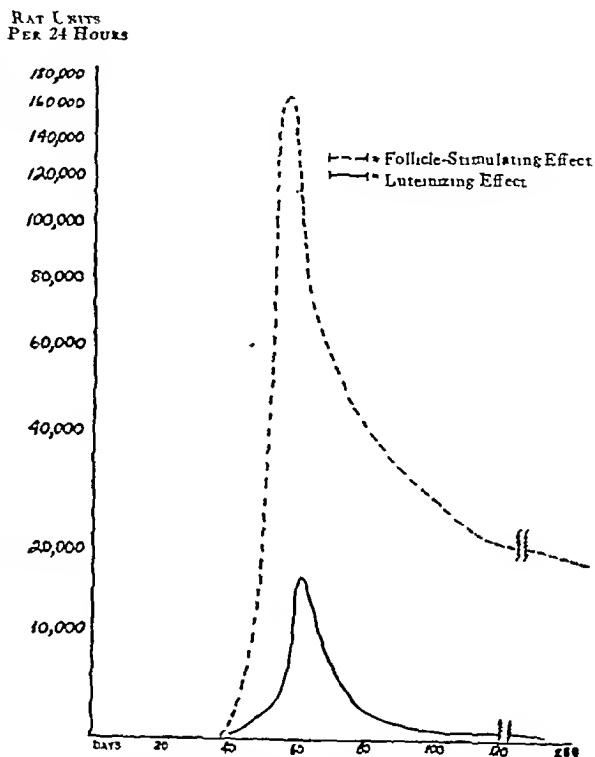

FIGURE 1 Urinary Excretion of Chorionic Gonadotropin during Pregnancy (Assayed on Rats)

development, but at present it is clear that the gonad-stimulating substances demonstrated in the urine of pregnant women by the Aschheim-Zondek test are at least largely of placental origin<sup>47-49</sup> Direct evidence of the formation of gonadotropin by placental cells was obtained by Jones, Gey and Gey,<sup>50</sup> who assayed this hormone from serially transplanted tissue cultures of these cells, in which the final explants were composed entirely of cells grown in vitro Although differences exist, this gonadotropin of placental origin is virtually identical with that of pituitary origin — hence the old designation anterior-pituitary-like (APL)<sup>45</sup>

The problem of whether this placental secretion is composed of one or two hormones similar to the pituitary follicle-stimulating hormone and luteinizing hormone is beyond the scope of the present paper Aschheim and Zondek demonstrated clearly

formed as long as four thousand years ago<sup>1</sup> Although many of the procedures advocated were mystical and apparently bizarre, one basic concept, intelligible from modern standards, arose in these early times and persisted to the sixteenth century — namely, the idea that urine from pregnant women stimulated plant growth These pregnancy tests based on the stimulation of plant growth and germination of seeds are still occasionally referred to in the relatively recent literature and have therefore been used for several thousands of years

Although the search for improved methods was constant, it was only in the early twentieth century that the pioneer work of Evans and his associates,<sup>2</sup> Smith and Engle<sup>3</sup> and Zondek and Aschheim<sup>4-6</sup> made possible the present era of accurate pregnancy diagnosis The demonstration by these authors of the complex inter-relation between the ovary and the pituitary body and the urinary reaction of these hormones produced for the first time the tools necessary for basing pregnancy diagnosis on sound scientific grounds In 1928 the epochal description of the Aschheim-Zondek<sup>6</sup> test appeared, reactivating interest in rapid, accurate diagnostic tests of pregnancy

Diagnostic laboratory procedures suggested by Abderhalden,<sup>7</sup> Kamnitzer<sup>8</sup> and Roubitschek<sup>9</sup> antedated somewhat the Aschheim-Zondek test However, by present standards, these tests were grossly inadequate and have long since been mostly forgotten

The Aschheim-Zondek test provided, for the first time, a means of diagnosing early pregnancy that was almost 100 per cent accurate Its accuracy remains unsurpassed to this day Since the description of this pioneer test, many variants have been proposed, all designed to cut down the time required for the performance of the test The Friedman test,<sup>10</sup> originating two years after the Aschheim-Zondek test, represents a simple modification employing isolated female rabbits With the use of this animal the time required for obtaining a diagnosis was cut from five to two days

Despite the widespread adoption of the Friedman test and its high degree of accuracy, the time element that it required remained a compelling force for further improvement In 1933 Shapiro and Zwarenstein<sup>11</sup> presented before the Royal Society of South Africa a new test for pregnancy, utilizing for the first time an amphibian, the female South African clawed frog (*Xenopus laevis*) The time for a reaction was reduced to within twenty-four hours, but the unavailability of the frog unquestionably blocked, to some extent, the widespread adoption of this technic However, this very valuable observation — namely, that amphibians would react to mammalian hormones — served as the forerunner of other frog tests, described below

With the knowledge that hyperemia is one of the first detectable changes produced in the ovary of infantile rats by gonadotropins, numerous investigators have adopted this tissue change as a criterion for a positive pregnancy reaction<sup>12-21</sup> Starting with procedures advocated by Eberson and Silverberg<sup>12</sup> and Reiprich,<sup>13</sup> in which the hyperemic change was read at an approximate twenty-four-hour interval, use as an endpoint earlier and more subtle color differences, the time has been reduced to two hours, in the form of the Kupperman-Greenblatt<sup>21</sup> test As might be anticipated, however, as the time for reading the reaction has been shortened, the color changes have become more and more slight This difficulty in reading the endpoint constitutes a serious block to the widespread acceptance of this technic

Within the past two or three years a totally new method of pregnancy diagnosis has developed utilizing male frogs It was shown by Robbins and Parker<sup>22</sup> that the reaction of the male frog to gonadotropic hormone could be easily demonstrated by microscopical examination of cloacal fluid The appearance of sperm indicated a positive reaction Perhaps even more significant, however, was the fact that this reaction occurred quickly, usually within the four-hour period following the administration of the hormone The use of this reaction for a diagnostic test for pregnancy was obvious, and within the past year Mainini<sup>23</sup> has suggested a technic using a South American species of toad (*Bufo arenarum henseli*), and soon thereafter Wiltberger and Miller<sup>24</sup> and Robbins and Parker<sup>25</sup> demonstrated that the common North American frog (*Rana pipiens*) was equally suitable

By the use of the *Rana pipiens*, laboratory diagnosis of pregnancy could be carried out within two hours, frequently sooner, and the endpoint was absolutely clear cut, sperm being either present or absent From these early experimental reports, it appears that the procedures have great promise, offering economy and speed as well as accuracy How well they will stand up under widespread clinical trial remains to be seen

Chemical procedures capable of performance in a test tube and obviating the inconveniences of animal tests have long been sought The urinary histidine test, reported by Voge<sup>26</sup> soon after the original description by Aschheim-Zondek, more recently studied in great detail by Kapeller-Adler and Haas,<sup>27-29</sup> has not achieved wide acceptance Young,<sup>30</sup> Seidman<sup>31</sup> and Krieger,<sup>32</sup> among others, doubted its value since it fell far short of the accuracy of the Aschheim-Zondek test and, moreover, had little value for the diagnosis of early pregnancy, being of chief value in the later stages of pregnancy The Visscher-Bowman<sup>33</sup> test, a color reaction that was first described in 1934, appears, in the light of clinical trial, to have little usefulness

sitive than the rat or mouse, on a gram for gram basis, however, its large bulk necessitates such large dosage of hormone that its relative sensitivity is of little practical advantage

As for the frog, work is still in the developmental stage. However, it appears that the female *Xenopus laevis* as well as the male *Bufo arenarum* and *Xenopus laevis* respond to the luteinizing hormone of the chorionic gonadotropin, the first by the extrusion of the ova, and the last two by the emission of spermatozoa. Although there are other substances to which the frogs will react, they do not interfere with the use of these animals for pregnancy diagnosis, since they are never encountered in the course of pregnancy.

Mainini<sup>23</sup> states that the *Bufo arenarum hensel*, the South American toad advocated by him for pregnancy diagnosis, will react to 40 international units of gonadotropin. From work performed in this laboratory<sup>56</sup> it appears that the average male *Rana pipiens* will react to the same dose of chorionic gonadotropin as the average immature rat, this apparent equal sensitivity, it should be noted, is not based on weight equality. However, it is of practical significance since it makes the individual *Rana pipiens* able to detect levels of hormone that up to now could only be detected by rats.

From the preceding brief summary it can be seen that the choice, performance and evaluation of a pregnancy test is not a simple matter. The choice of animal, in relation to the specific hormone to be assayed, is of great importance. The speed with which the target organ can react is constant and therefore predetermines the speed of the test, a factor of great importance in problems of therapy. The species sensitivity is of obvious significance, especially when one is dealing with hormone titers away from the peak period of elimination of hormone. Thus the immature rat becomes the animal of choice in urines or serums of probable low hormonal titer, especially when the titer of the pregnant urine is so low as to produce only follicle stimulation without the production of true corpora lutea.

#### COMMON TESTS

A list of pregnancy tests in use or developed during the past ten years is as follows:

##### Bio-assay technics

###### Rodents

Aschheim-Zondek technic<sup>6, 51, 57-59</sup>

Ovarian hyperemic test<sup>12-21</sup>

Ovulatory test<sup>60</sup>

###### Rabbits

Friedman test<sup>10, 61-63</sup>

###### Amphibia

Female *Xenopus laevis*<sup>11, 65-69</sup>

*Bufo arenarum hensel*<sup>23</sup>

*Rana pipiens*<sup>24, 25</sup>

Fish tests<sup>70</sup>

##### Chemical tests

Histidine tests — Kapeller-Adler<sup>27-29, 71, 72</sup>

Visscher-Bowman test<sup>33, 73, 74</sup>

Colorimetric test — Schmulowitz-Wylie<sup>27</sup>

Pregnanediol test — Guterman<sup>39, 75-77</sup>

##### Skin tests

Colostrum<sup>45, 76, 79</sup>

Placental extract (Grushkin)<sup>44, 80</sup>

Chorionic antuitrin-S test

(Gillfillen-Gregg)<sup>46, 80-82</sup>

Estrogen<sup>83</sup>

##### Miscellaneous technics

Pupillary test (Bercoffitz)<sup>84</sup>

Prostigmine<sup>42, 85</sup>

This list by no means includes all the technics developed since the advent of the Aschheim-Zondek test. Rather, it is intended to include either tests in current use, as indicated by the recent literature of the past ten years, or procedures that have appeared in the past ten years and have yet to be evaluated.

##### Aschheim-Zondek Test<sup>6</sup>

The oldest of all the so-called "modern" pregnancy tests, this remains to date one of the most widely employed and certainly one of the most accurate technics. As originally described it employs immature mice weighing 8 gm and approximately three weeks of age. Filtered morning urine, in amounts of 1.8 to 2.4 cc, is administered to each mouse in individual doses varying from 0.3 to 0.5 cc three times daily for two days. Ninety-six hours after the first injection the animals are sacrificed, and the ovaries examined for "blutpunkte," or corpora hemorrhagica, a change produced by the presence of chorionic gonadotropin in the urine. In some laboratories the immature rat has been substituted for the mouse because of its greater sensitivity to the hormone and resistance to toxic factors in the urine. Rats twenty-one to twenty-three days old are injected with 6 cc of urine given in 1-cc doses twice daily for three days. The animal is sacrificed on the fifth day, and the ovaries examined for follicle formation and corpus luteum formation. Corpora hemorrhagica are rarely found in the rat. In this laboratory, the presence of corpora lutea, indicating the presence of luteinizing hormone, is required as the minimum evidence of a pregnancy reaction. However, as has been described very early in pregnancy, follicle formation may occur alone in the rats' ovaries because the development of a follicle-stimulating effect antedates the appearance of the luteinizing effect in the first few weeks of pregnancy. Hence, in problems of the diagnosis of very early gestation, the follicle reaction, although not definitive, may well be the harbinger of a developing luteal reaction. The same cycle is followed in reverse at the time of delivery or of fetal

that two distinct changes occurred in the ovaries of the rat after the administration of urine from a pregnant woman. These organs responded either to two different hormones or to one hormone in two different ways, first by follicle formation and secondly by luteinization and the development of corpora lutea. As a result, when the rat is used for the determination of the titer of placental hormone during pregnancy two distinct endpoints must be followed, producing as it were two separate curves for gonadotropin production during pregnancy. The first endpoint is reached at the highest dilution of the urine that will produce definite corpora lutea formation. Beyond this dilution definite follicle formation is still present. The second endpoint is reached only when definite follicle formation is extinguished (Fig 1).

From this graph it can be seen that there is a considerable lag after conception, during which little hormone production can be detected. A rapid rise ensues, to a peak at approximately seven or eight weeks of gestation, followed by a rapid fall, so that in the last trimester levels of gonadotropic hormone are low. It is, therefore, perfectly possible to obtain a negative pregnancy reaction during the

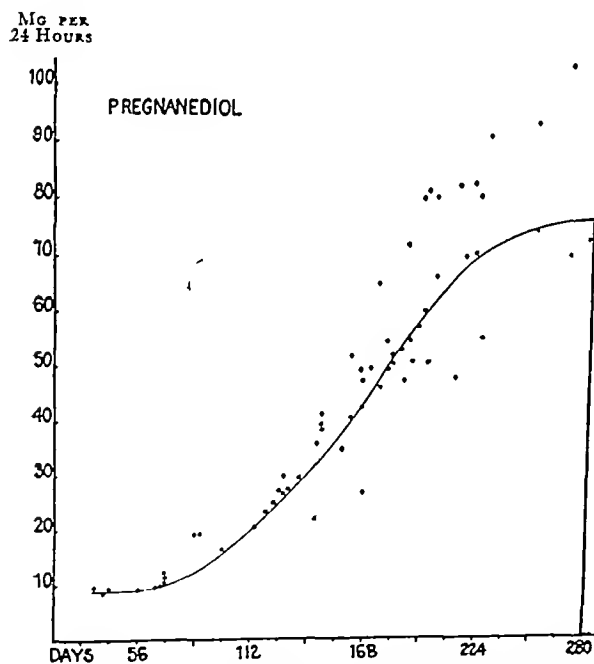

FIGURE 2 Urinary Excretion of Pregnanediol in 8 Cases of Normal Pregnancy (Reproduced from Penning<sup>53</sup> by Permission of the Publishers)

last trimester in the obvious presence of a living fetus. It is, moreover, very important to note that the follicle-stimulating effect begins first and is well marked at a time when virtually no luteinizing effect is present, and that it remains at a much higher titer throughout pregnancy. The importance of these facts is brought out below in a consideration of the so-called weakly positive test.

Other hormones produced in increased amounts during pregnancy are estrogen and progesterone, the latter forming the basis of an important chemical pregnancy test, the Guterman test for pregnanediol. Ample evidence exists to establish the fact that the placenta, in both man and animals, as well as the ovaries, forms these substances<sup>51,52</sup>. In fact, in the last months of the gestation, after the corpus luteum of the ovary degenerates, the placenta is the chief source of progesterone. Unlike the gonadotropins, these substances show progressively rising titers throughout the period of gestation and pass through no peak, abruptly falling either shortly before or at the time of delivery. Since the progesterone elimination almost exactly parallels the estrogen excretion, a curve of the latter substance will suffice to show the distribution of both hormones during pregnancy (Fig 2). It is therefore apparent that excretion of progesterone — that is, pregnanediol — will be least in the early stages of pregnancy and progressively more well marked in the later stages.

That pregnancy hormones will produce changes in lower animals is now well known<sup>54,55</sup>. Zondek and Aschheim<sup>54,55</sup> have classified the ovarian changes produced by gonadotropins as follows:

- APR I — follicle ripening and induction of vaginal estrus
- APR II — hyperemization of ovary and follicle hemorrhage
- APR III — formation of corpora lutea  
(APR = anterior pituitary reaction)

These gonadotropic reactions occur in a fixed sequence, with relatively fixed time relations, dependent only on the species of animal used, the type of hormone and the route of administration of the hormone. That is to say, the size of the dose and conditions of maintaining the animal have relatively no effect on the speed of the reaction. The first gross effect is hyperemization of the ovary, shortly thereafter, swelling, followed by ovulation, occurs, in turn followed by lutea formation. Up to recent date, the three animals most widely used for laboratory diagnosis of pregnancy have been the mouse, rat and rabbit. Each of these animals reacts in its own more or less characteristic fashion to the administration of gonadotropic hormone — the mouse and rabbit by the formation of corpora hemorrhagica, and the rat by the formation of cystic follicles that later become luteinized. Follicle hemorrhage or corpora hemorrhagica are rarely seen in the rat. Moreover, it is also known that the congestion and reddening of the ovaries (APR II) is most readily seen in the rat, the only animal in which the ovaries, at rest, are quite anemic. Species differences in sensitivity to chorionic hormone also occur; thus, for a given weight, immature rats are twenty-five times more sensitive to chorionic gonadotropin than mice. The rabbit in turn is more sen-

CASE RECORDS OF THE  
MASSACHUSETTS GENERAL HOSPITAL

Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C CABOT

TRACY B MALLORY, M D, Editor

BENJAMIN CASTLEMAN, M D, Associate Editor

EDITH E PARRIS, Assistant Editor

CASE 34351

PRESENTATION OF CASE

A two-and-a-half-year-old girl was apparently well until six days before admission to the hospital when her parents noted that she walked about bent over as if in discomfort and tended to draw the right leg upward. Except for some decrease in appetite and easy fatigability for several weeks she had no symptoms. Her birth and development were uneventful, and she had had none of the usual childhood diseases.

Physical examination revealed a well developed and well nourished child. The heart and lungs were

normal. There was no peripheral lymphadenopathy. Largely filling the right abdomen and extending from costal border to below the iliac crest and across the midline at the level of the umbilicus was a firm, smooth, fixed, nontender mass, which was not lobulated.

The temperature was 99.8°F. The blood pressure was 110 systolic, 80 diastolic.

The urine specimen concentrated to 1014, and there was no albumin or sugar. One white cell per high-power field was seen. The white-cell count was 9800. The serum protein was 7.2 gm, and the nonprotein nitrogen 31 mg per 100 cc. X-ray studies of the chest, skull and femurs were negative except for some elevation of both sides of the diaphragm. An intravenous pvelogram showed a huge ovoid mass in the right abdomen. This extended well to the left of the spine, and the tip was over the iliac crest. The mass was somewhat lobulated, and there was a suggestion of minute calcium specks at its lower pole. The liver was thought to be displaced upward. Both kidneys were promptly visualized, and the left appeared normal. The right renal calyces were displaced upward, and the ureter was displaced toward the midline and somewhat posteriorly. The renal drainage was normal.

On the fifth hospital day an operation was performed.

death. Hence, the luteinizing effect disappears before all follicle formation is lost. The value of the follicle-stimulating reaction is therefore quite obvious in questions of intrauterine fetal death and missed abortion. It is of importance to remember that elevations of pituitary follicle-stimulating hormones accompany the menopause, hence, any interpretation of these follicle changes in the rat ovaries can only be made against the background of a proper clinical history. By the use of either the immature mouse or rat, the results obtained with the Aschheim-Zondek test are universally reported as excellent. Aschheim,<sup>57</sup> in 1935, cited his accuracy as 98 per cent in positive reactions and 99.5 per cent in negative tests.

Mazer and Goldstein<sup>51</sup> reported on the results of 11 independent groups with correct positive reactions in 94 per cent and correct negative reactions in 97 per cent of the cases. Mack and Agnew<sup>58</sup> likewise compiled a series of 8685 cases tested by the Aschheim-Zondek technic with an accuracy of 96.6 per cent. In this laboratory, where equivocal ovarian changes in the rat are controlled by microscopical section and examination, the accuracy has closely approximated 100 per cent, only one false report having occurred in the past many years.

It is, therefore, not without reason that the Aschheim-Zondek test has remained a constant favorite. Its accuracy, reliability and sensitivity in well trained hands are goals for other procedures to attain. The one drawback to this procedure, aside from the necessity of maintaining rodents of proper size and age, has been the time required for the performance of the test—four or five days. As stated above, this time interval is fixed by the fact that it requires ninety-six hours for the ovaries of mice to form corpora hemorrhagica and one hundred and twenty hours for the rat ovaries to form corpora lutea.<sup>51, 55</sup>

So my diagnosis has to be a malignant tumor arising from the retroperitoneal space and invading the liver

### CLINICAL DIAGNOSIS

Neuroblastoma

### DR REYERSBACH'S DIAGNOSIS

Malignant tumor arising from retroperitoneal space and invading the liver

### ANATOMICAL DIAGNOSIS

*Hepatoma of liver*

### PATHOLOGICAL DISCUSSION

DR OLIVER COPE The X-ray Department actually favored a diagnosis of Wilms's tumor. The Surgical Service diagnosed it as neuroblastoma. However, we both agreed that it was retroperitoneal. In operating I thought it wise to approach it transperitoneally through the flank. It was not a neuroblastoma and had nothing to do with the kidney. So far as we could determine at operation it was a primary tumor of the liver and it was so large that it gave the impression of a retroperitoneal tumor. It arose in the right lobe of the liver and had grown upward and backward and appeared on the dome of the liver, with normal liver in front. The tumor invaded the left lobe to such an extent that it would be impossible to excise it without also excising the portal vein. Therefore excision seemed impossible in spite of the fact that we could have saved the left hepatic artery. There was no evidence of metastases or of a primary tumor elsewhere. It was such an unusual situation that we asked Dr Castleman to come to the operation and view it in its entirety. I presented him with a specimen, and that in itself was a major procedure because this was a very vascular tumor and it was difficult to control the hemorrhage.

DR BENJAMIN CASTLEMAN The piece that Dr Cope gave me was 15 cm in diameter, which was fairly large considering how friable the tumor was. I did a frozen section and thought that the best diagnosis was a primary liver-cell carcinoma, or a hepatoma, rather than a metastasis from a neuroblastoma. Neuroblastoma may metastasize to the liver and produce a large mass. Usually there is more than one tumor nodule. Here the mass seemed to be continuous from right to left. There was no surrounding cirrhosis, which one usually sees with hepatoma in adults, the cirrhosis being the predisposing cause of the hepatoma. That apparently is not true in hepatomas arising in children. I had never seen one in a child but Steiner,<sup>1</sup> who reviewed all the cases up to 1938, was able to collect over 70 cases of primary liver-cell carcinoma in children under sixteen years of age. It is interesting that over half these were in children under two years of age. He reported that there was no

cirrhosis associated with these cases, so that the etiology is probably congenital. He described a case in which the hepatoma was present at birth. The hepatomas in children are usually very malignant, and according to Steiner the average duration of life is four months after the tumor is discovered. The resections that had been done in those cases were unsuccessful although there have been some cases of hepatoma successfully removed both in adults and children. I can recall one that Dr Sweet<sup>2</sup> removed from a seventy-five-year-old physician. He was seen by Dr Sweet three years later and found to have nodules in the right upper abdomen, which were probably recurrences or metastases. However, he continued to practice during this three-year period.

### CASE 34352

#### PRESENTATION OF CASE

A thirty-six-year-old housewife entered the hospital with the chief complaint of difficulty in breathing.

For sixteen years prior to admission the patient thought she had had slight difficulty in swallowing food. Three years before entry a physician gave her belladonna because of a sensation of "food sticking in the throat." At this same time she began to have right-upper-quadrant postprandial distress, which disappeared when she was placed on a low-fat diet. About three years before entry she first became aware of dyspnea with the exertion of prolonged talking. She disregarded this, however, until eight months before admission when she had a sudden increase in dyspnea with loss of the voice. She believed that these difficulties came from the trachea just below the larynx, and found that she was partially relieved if she pulled the skin of the neck forward. The severe dyspnea gradually improved after a month but at the time of admission she was still aware of difficulty in drawing her breath and had a loose cough productive of white phlegm, sometimes with lumps of greenish matter in it but never blood. Food occasionally caught in the throat and at such times the patient had a sense of fullness under the mid-sternum.

The past history and review of the systems were essentially noncontributory.

Physical examination disclosed a well developed, well nourished woman who had evident respiratory distress with prolonged inspiration. She was not particularly hoarse. The thyroid gland was felt to be two and a half to three times enlarged but was symmetrical, soft, smooth and nontender. No

## DIFFERENTIAL DIAGNOSIS

DR GERTRUD C REYERSBACH This child obviously had a large right-sided abdominal tumor. We are asked to determine the type. I think it is possible to exclude certain conditions, such as duplication of the bowel, tumor of the pancreas, hydronephrosis, polycystic kidney and tuberculous lymphadenitis, without further discussion. There are no data to indicate that this child had an ovarian tumor. In lymphosarcoma one would expect a somewhat different clinical picture. In the absence of disturbances of the endocrine system we may exclude a suprarenal cortical tumor. Could this mass have been a Riedel's lobe of the liver? There are several reasons not to think so: the mass described was too large, there were signs of general involvement, and an operation was performed.

The history in this case is compatible with several conditions: neuroblastoma, which arises from cells of the sympathetic nervous system and is the most common neoplasm of the abdominal cavity in early childhood; Wilms's tumor, which is a congenital embryonal mixed tumor arising from the kidney anlage, and unattached retroperitoneal embryoma.

All these conditions are malignant and most frequently make their appearance during the first years of life with a peak between the second and third years. Actually this does not quite hold for the unattached retroperitoneal embryoma, which may be discovered later. In neuroblastoma and Wilms's tumor the first thing usually discovered is the abdominal mass, as in this child. The mild constitutional symptoms — namely, anorexia, fatigability, and the lack of cachexia — are typical of all conditions. Likewise, the sudden discovery of a large mass is typical of these conditions. It is due either to the fact that the mass was overlooked previously or that it had grown rapidly in a short while, such rapid growth is sometimes due to bleeding into a Wilms's tumor. The absence of urinary findings and the distortion of the renal pelvis on x-ray study are frequently seen in all three lesions. The unattached retroperitoneal embryoma usually grows on either side of the vertebral column from as high as the fourth cervical segment down to the internal genitalia. Its location is different from the one described here, and it is extremely rare. I am going to exclude it.

In favor of neuroblastoma are the symptoms of anorexia and fatigability, the presence of the mass on the right side, calcification in the tumor as seen on x-ray examination and displacement of the renal pelvis. Against it is the fact that the mass was described as oval and smooth, most neuroblastomas are described as nodular — certainly those that I have seen have been nodular. Also, the patients that I have observed showed anemia and fever at

the time the tumor was discovered. This child's temperature was only 99.8°F.

What is in favor of Wilms's tumor? The symptoms of anorexia, fatigability and displacement of the renal pelvis hold for this tumor also, and x-ray evidence of calcification is also described in Wilms's tumor. The mass is smooth and the border well delineated. Against it is the extension beyond the vertebral column.

I think that the child might have either of these two tumors. Both start retroperitoneally, and in this abstract there is a note saying that the mass arose from the costal margin. That puzzles me. I do not know how to interpret it. I do not know whether the neuroblastoma had metastasized to the liver, but I hope that the x-ray films will give some help.

DR STANLEY M WYMAN The mass is fairly well outlined, somewhat smooth and slightly lobulated. It extends past the midline to the left, down to the brim of the pelvis as well as upward to the costal margin, approximately filling the entire right midabdomen. The areas of calcification are fairly well seen, particularly in the lower pole of the mass. The film taken after the injection of dye shows good outlining of the right calyceal pattern. An interesting finding is that the calyces are displaced upward, but show no significant distortion or apparent invasion. The pelvis and ureter follow a relatively normal course. This film is an oblique view showing the mass lying somewhat anteriorly. The left margin can be well outlined, and the mass appears more anterior than posterior. In no film can one outline the lower margin of the right kidney. This mass cannot be differentiated from the kidney shadow, with which it appears continuous. The lateral view adds no appreciable information. The lungs appear clear. The bones as visualized show no evidence of destruction.

DR REYERSBACH Do you think that the mass is attached to the liver?

DR WYMAN I cannot say. I cannot identify the liver accurately per se. The lower border fades into this mass, and I cannot say whether it is a part of the mass or is overlying it. I cannot differentiate the liver from the mass any more than I can the kidney from the mass.

DR REYERSBACH Your statement that the mass appears to lie anteriorly makes me more discouraged. Both Wilms's tumor and neuroblastoma arise from the retroperitoneal space and are posterior. When I read over the abstract I looked up other tumors that would be more anterior, and they are extraordinarily rare. A tumor of a rib would not behave in that way. Any tumor of the liver in childhood is very rare. There is no indication that the child had an echinococcus cyst. Hemangiomas are usually small and probably would be discovered accidentally.

I am obliged to leave the diagnosis as a malignant tumor of the upper mediastinum

DR BENJAMIN CASTLEMAN Does anyone want to come a little closer to the diagnosis?

DR ALFRED KRANES The patient had an enlarged thyroid gland and pressure symptoms. I do not understand why Dr Lerman discounted the thyroid gland so readily. Did he do so simply because the gland was soft?

DR LERMAN It was soft, smooth, nontender and without any nodules whatever.

DR KRANES Would you agree that it was soft, Dr Lurie?

DR LURIE It was soft.

DR OLIVER COPE It takes considerable pressure to close the trachea off. The thyroid gland does it under two circumstances: in goiters that are fibrous, hard and invasive, as in either thyroiditis or carcinoma, and when the goiter is low enough to get caught in the upper thoracic strait. Dr Lerman is justified in eliminating the thyroid gland—either the goiter was not the cause or the description of it was wrong.

DR KRANES I had assumed that the description was wrong.

DR COPE Malignant lesions in the trachea and esophagus invading the underneath capsule of the thyroid gland should be mentioned. We have had rare cases of that type. We had a case in which the disease apparently arose as a sarcoma of the trachea and invaded the thyroid gland and gave rise to this type of compression. We had 2 cases that I can remember from the esophagus. In both the esophageal cases the primary lesion was overlooked, and a diagnosis of carcinoma of the thyroid gland made. It was not until operation that the primary etiology was disclosed. Dr Lerman is right in thinking of a malignant tumor elsewhere than the thyroid gland, and the upper mediastinum is a good location except that in this case we do not see it in the x-ray films.

DR LERMAN By the same reasoning, there is no x-ray evidence to point to the esophagus or trachea and such diagnoses would be pure guesswork.

DR COPE In the 2 cases that I mentioned the invading lesion was small and overlooked in the x-ray films.

DR EDWARD B. BENEDICT We had a case of a papillary tumor of the thyroid gland that invaded

the trachea and produced symptoms of dyspnea, hemoptysis and wheeze, which on bronchoscopy turned out to be a primary epidermoid carcinoma of the trachea.

DR LURIE When I first saw this woman my impression was that the lesion was entirely intralaryngeal. She had difficulty in inspiration and expiration but was able to do her work. When I looked at the larynx I was amazed to see that it had a fair airway, and the vocal cords anteriorly seemed to be lying in a reddened mass of mucous membrane that had bulged upward. With the larynx in complete abduction, a semi-doughnut projection of the trachea itself was seen. That made me think of rhinoscleroma, a very rare lesion—we have seen 4 or 5 cases in the Eye and Ear Infirmary. As I looked at this I debated a good deal whether I was justified in going in and trying to remove a piece of this mucous membrane through the larynx so that we could make a diagnosis. If we did that, I would have had to do a tracheotomy. If I did not succeed in getting a specimen, we were no better off than before. Having decided that, I began to wonder whether there was an extrinsic cause, and my first guess was the thyroid gland, especially a growth of the superior pole invading the larynx. I remember a case about twenty-five years ago in which I missed the diagnosis completely in trying to remove the tissue through the larynx and the patient died a year later from cancer of the thyroid gland. I finally asked Dr Richard H. Sweet to explore externally, and a thyroidectomy was done.

#### CLINICAL DIAGNOSIS

Carcinoma of thyroid gland, with invasion of trachea

#### DR LERMAN'S DIAGNOSIS

Malignant tumor of upper mediastinum, with compression of trachea

#### ANATOMICAL DIAGNOSIS

*Adenoma of trachea, with extension into thyroid gland*

#### PATHOLOGICAL DISCUSSION

DR CASTLEMAN I was present at this operation. The thyroid gland was symmetrical and slightly enlarged and on section was not remarkable. On

nodules were felt. Laryngoscopic examination revealed swollen mucous membranes of the vocal cords without impairment of function or tumor, and the tracheal mucosa below the larynx was reddened and edematous, with narrowing of the lumen apparently by extrinsic pressure.

Examination of the blood revealed a red-cell count of 4,400,000, with a hemoglobin of 12.2 gm, and a white-cell count of 6800, with 46 per cent neutrophils, 40 per cent lymphocytes, 6 per cent monocytes and 8 per cent eosinophils. The total protein was 5.7 gm per 100 cc, and the prothrombin time 17 seconds (control, 16 seconds).

X-ray films of the neck and chest showed marked narrowing of the trachea opposite the lower cervical and upper thoracic spine. There was a soft-tissue density adjacent to the upper thoracic spine on the left, which may have represented the subclavian vessels. No obvious retrosternal extension was seen. The lung fields were clear, and the heart was of normal size.

On the fourth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR JACOB LERMAN: I should like to see the x-ray films.

DR STANLEY M. WYMAN: The only films available are those of the chest, which show a definite area of narrowing in the upper trachea, at about the level of the sixth and seventh cervical and the first thoracic vertebrae. This narrowing is rather symmetrical and smooth. The detail, however, is not adequate to make much more of a statement than that. The prominence of the vascular tree in the mediastinum is seen on the left and appears to represent a prominent left subclavian artery, on the right there is no unusual prominence. The chest itself appears essentially normal. One cannot outline a definite mass in the lower part of the neck.

DR LERMAN: Is there anyone here who can verify the description of the thyroid gland? Was it soft, smooth and symmetrical?

DR MOSES H. LURIE: Yes. A barium swallow was done at the Eye and Ear Infirmary, and there was no evidence of outcropping.

DR LERMAN: I found on reading the protocol that I was thinking in terms of aneurysm of the aorta or of the great vessels. After seeing the

x-ray films I am obliged to discard this diagnosis completely.

The obvious place to look for trouble is the thyroid gland, although I am almost convinced that that was not the source of symptoms. I shall merely mention the various possible types of thyroid tumors that may produce such symptoms, particularly when such a gland encircles the trachea. A smooth goiter, a colloid goiter, with or without nodules, may encircle the trachea and produce compression with difficulty in breathing and the portion of the thyroid gland lying between the trachea and esophagus may also produce difficulty in swallowing. The more common type of thyroid tumor that does this is the result of chronic thyroiditis, either the Hashimoto or the Riedel type. However, from the description one has to exclude thyroiditis, which is a hard mass and often irregular. Similarly the description does not fit thyroid cancer, which is also a common cause for compression of the trachea. Either adenocarcinoma or papillary adenocarcinoma may produce compression by encircling the trachea. Either would produce a very hard, irregular tumor with evidence of tumor elsewhere in the neck or distally. In spite of the fact that the protocol emphasizes the importance of the thyroid swelling, I am forced to discard it as a source of symptoms.

What are the other possibilities? Anomalous vessels should be mentioned. There is not much evidence by x-ray examination or from the history, but anomaly of a large vessel could compress the trachea. However, such a condition would be discovered early in life. Benign mediastinal tumors, particularly benign cysts, most commonly dermoid cyst or teratoma, may produce compression of the trachea. More likely, because of the extensive involvement, a malignant mediastinal tumor has to be considered, such as lymphoma, sarcoma and so forth. I am afraid I cannot narrow it down further than this. I believe that the clinical and the x-ray evidence caused the surgeons to go after the thyroid gland as the cause of compression, but I am forced to conclude that there was a tumor in the upper mediastinum.

I should mention esophageal tumors, although the esophagus did not seem to play too large a role. Diverticulum of the esophagus producing compression of the trachea is a possibility. Also carcinoma of the esophagus is possible but unlikely.

I am obliged to leave the diagnosis as a malignant tumor of the upper mediastinum

DR BENJAMIN CASTLEMAN Does anyone want to come a little closer to the diagnosis?

DR ALFRED KRAVES The patient had an enlarged thyroid gland and pressure symptoms. I do not understand why Dr Lerman discounted the thyroid gland so readily. Did he do so simply because the gland was soft?

DR LERMAN It was soft, smooth, nontender and without any nodules whatever.

DR KRAVES Would you agree that it was soft, Dr Lurie?

DR LURIE It was soft.

DR OLIVER COPE It takes considerable pressure to close the trachea off. The thyroid gland does it under two circumstances in goiters that are fibrous, hard and invasive, as in either thyroiditis or carcinoma, and when the goiter is low enough to get caught in the upper thoracic strait. Dr Lerman is justified in eliminating the thyroid gland—either the goiter was not the cause or the description of it was wrong.

DR KRAVES I had assumed that the description was wrong.

DR COPE Malignant lesions in the trachea and esophagus invading the underneath capsule of the thyroid gland should be mentioned. We have had rare cases of that type. We had a case in which the disease apparently arose as a sarcoma of the trachea and invaded the thyroid gland and gave rise to this type of compression. We had 2 cases that I can remember from the esophagus. In both the esophageal cases the primary lesion was overlooked, and a diagnosis of carcinoma of the thyroid gland made. It was not until operation that the primary etiology was disclosed. Dr Lerman is right in thinking of a malignant tumor elsewhere than the thyroid gland, and the upper mediastinum is a good location except that in this case we do not see it in the x-ray films.

DR LERMAN By the same reasoning, there is no x-ray evidence to point to the esophagus or trachea, and such diagnoses would be pure guesswork.

DR COPE In the 2 cases that I mentioned the invading lesion was small and overlooked in the x-ray films.

DR EDWARD B. BENEDICT We had a case of a papillary tumor of the thyroid gland that invaded

the trachea and produced symptoms of dyspnea, hemoptysis and wheeze, which on bronchoscopy turned out to be a primary epidermoid carcinoma of the trachea.

DR LURIE When I first saw this woman my impression was that the lesion was entirely intralaryngeal. She had difficulty in inspiration and expiration but was able to do her work. When I looked at the larynx I was amazed to see that it had a fair airway, and the vocal cords anteriorly seemed to be lying in a reddened mass of mucous membrane that had bulged upward. With the larynx in complete abduction, a semi-doughnut projection of the trachea itself was seen. That made me think of rhinoscleroma, a very rare lesion—we have seen 4 or 5 cases in the Eye and Ear Infirmary. As I looked at this I debated a good deal whether I was justified in going in and trying to remove a piece of this mucous membrane through the larynx so that we could make a diagnosis. If we did that, I would have had to do a tracheotomy. If I did not succeed in getting a specimen, we were no better off than before. Having decided that, I began to wonder whether there was an extrinsic cause, and my first guess was the thyroid gland, especially a growth of the superior pole invading the larynx. I remember a case about twenty-five years ago in which I missed the diagnosis completely in trying to remove the tissue through the larynx and the patient died a year later from cancer of the thyroid gland. I finally asked Dr Richard H. Sweet to explore externally, and a thyroidectomy was done.

#### CLINICAL DIAGNOSIS

Carcinoma of thyroid gland, with invasion of trachea

#### DR LERMAN'S DIAGNOSIS

Malignant tumor of upper mediastinum, with compression of trachea

#### ANATOMICAL DIAGNOSIS

*Adenoma of trachea, with extension into thyroid gland*

#### PATHOLOGICAL DISCUSSION

DR CASTLEMAN I was present at this operation. The thyroid gland was symmetrical and slightly enlarged and on section was not remarkable. On

its posterior aspect was grayish tissue that looked like connective tissue. It was hard and fibrous and did not look at all granular as it would have been with carcinoma. I did a frozen section on a piece of it and found a tumor made up of uniform round cells and obviously epithelial. It reminded me of the adenomas that one sees in the bronchus. Dr Sweet then found that the surface of the trachea was involved with this same tumor.

DR LURIE: I then did a tracheotomy and looked into the mucous membrane of the trachea underneath the surface of the larynx and found that it was edematous, but there were no outcroppings and nothing that suggested a tumor mass.

DR CASTLEMAN: Dr Sweet took a biopsy of the trachea, and our final microscopical sections confirmed the diagnosis of adenoma. The cells were arranged in small glands corresponding to what is often called the mixed-tumor type of adenoma rather than the more common carcinoid type. By the mixed-tumor type I mean the type that is similar to the mixed-tumor of salivary-gland origin, it also resembles the cylindroma or epithelioma adenoides cysticum variety of the basal-cell epithelioma. This could be called a low-grade adenocarcinoma because it has invaded and infiltrated the posterior portion of the thyroid gland. I think we can say that the patient had had the tumor since the first symptoms began, sixteen years previously. It was very slowly growing and acted as any adenoma of the bronchus. There is still plenty of tumor left in the tracheal wall. We see adenomas of the bronchus with more tumor extrinsically than intrinsically, and it is not surprising that there was little intrinsic tumor in the trachea here. The problem arises regarding what should be done—whether a total laryngectomy should be performed or whether one should continue to follow her, knowing that the tumor is slowly growing but may metastasize to a regional lymph node and cause further difficulty by mediastinal spread.

This is the second case of tracheal adenoma that we have had here. The other was also of the same type and one that we diagnosed as epithelioma adenoides cysticum. It was in a man of sixty-eight who had had a local removal of the tumor two years previously, after having had symptoms for six months. Recently he developed a recurrence with

symptoms of marked dyspnea, wheeze and hemoptysis. Dr Sweet was able to resect a portion of the trachea, including a pedunculated tumor, 2 cm long, attached on a 6 mm base.

DR JOHN STANBURY: If she had a total thyroidectomy, what was the consistence of the thyroid gland?

DR CASTLEMAN: It was perfectly soft. The entire gland was removed. The only place it was not soft was on the posterior aspect, which was involved with tumor.

DR BENEDICT: I might mention that in looking up the literature, I found 507 cases of primary carcinoma and 19 adenomas of the trachea. We have had 30 adenomas of the bronchus all of which were in the major bronchi. I just asked Dr Lurie why he did not do a bronchoscopy and he said that he could not.

DR LURIE: We could have, but we would have had to do a tracheotomy right away. I thought from the way the patient acted and from the x-ray studies that the lesion was better handled by an external rather than an internal approach. To get some of this specimen I would have had to go through the entire thickness of the mucous membrane of the larynx and trachea.

DR BENEDICT: And there was no adenoma in the trachea?

DR LURIE: Nothing that I could demonstrate. She now has a tracheotomy tube, and the swelling in the larynx and trachea is gradually going down. The breathing space is better than it was before operation.

DR CASTLEMAN: Have you anything to add, Dr Schall?

DR LEROY A. SCHALL: This case has been covered so thoroughly that I do not believe I have anything to contribute. I saw the patient before operation and ruled against a bronchoscopy because of the swollen mucous membrane. I also thought that it was a surgical case and should be approached externally.

DR LURIE: Why do you think that a laryngectomy would cure the case? Was there infiltration in the esophageal wall?

DR CASTLEMAN: It is possible that there was invasion of the esophagus. I do not believe it was determined at operation.

## THE THORNDIKE AND ITS CASTLE

SOME twenty-five years ago the Thorndike Memorial Laboratory of the Boston City Hospital was formally opened by His Honor James Michael Curley. This laboratory, dedicated to clinical research, was made possible through the generosity of George L. Thorndike (born in Salem in 1847), an alderman of the City of Boston. It has continued to function through the years—for the public good, let it be remembered—owing partly to the foresight and good will of Mr. Curley and partly to the wisdom of its successive directors—Francis W. Peabody, George R. Minot and William B. Castle.

In a very literal sense this laboratory existed and functioned two years before its public dedication

in 1924, though much of the actual investigative work was carried on elsewhere, for the building was not then completed. One member of the staff worked in the private laboratory of Otto Folin (somehow he was neither Doctor nor Professor but simply and respectfully Otto Folin), who kept his notes on the backs of old envelopes and lectured in a superbly simple style.

Now there is more to this hospitality of Otto Folin than meets the eye. Then, as now, there was a close and cordial relation between the Thorndike and the Harvard Medical School. It was intended to be a co-operative enterprise and indeed it was. From the very start Francis Peabody made it clear to his staff—there were but four—that as their statures grew and as their interests changed there were open to the Thorndike men several channels of endeavor—the School, the Wards and the Laboratory. Yet the beginning and the end, the alpha and omega, were the same—the welfare of the patient. Francis Peabody wrote not long before his death: "What we need is less of the system and law that kills and more of the spirit that gives life." That spirit has always prevailed.

Basic research has its place. Without it progress would stand still, but beyond any question there must also be clinical investigation. And for clinical investigation there must be patients. For each there must be money. From the City of Boston come the patients, through the far-sighted generosity of the city officials comes, in large measure, the money and thus also comes the opportunity to investigate, and so to help, our fellow men.

Yet with all these golden opportunities the work of the Thorndike, now internationally known, would come to naught were there not wise and sympathetic medical guidance. There are problems of administration, problems of personnel and, of course, the decision as to what research shall be done by whom and in what manner. Such things require time, tact, knowledge, wisdom and considerable self-sacrifice.

The Thorndike has been especially fortunate in its directors. Each has had his own individuality and peculiarities.

The first, Francis Weld Peabody, brave soul that he was, needs praise from no man. With a subtle

force he launched the Thorndike on its course and early in its career laid down the major principle that the Laboratory, the Wards and the School were to be dedicated to one end—the education of the physician and the material benefit of the patient

After Dr Peabody's tragic and untimely death the directorship passed to his good friend, George Richards Minot, who was awarded the Nobel Prize not so very long after another good friend had said "Poor George, still stuffing his patients full of liver when you and I know it's quite useless" Dr Minot is a man of very varied interests. Being a horticulturist and botanist, he is justly proud of his garden and especially of his magnificent irises. He is a prolific writer of letters and there flows from his office a veritable flood of major and minor missives to friends and acquaintances all over the world. The only thing he dislikes is inactivity either in himself or in others. If Dr Peabody's motto was "*Do something useful*," Dr Minot's is "*Do something*." Those who have the good fortune to know him will recognize that in his heart of hearts he is a very kindly and a very thoughtful man. It is common knowledge that in spite of serious personal illness and in the face of many disappointments he had the faith, persistence and patience to further his own clinical investigation with patients on the wards and thus to initiate and perfect the therapy of Addisonian anemia. Dr Minot merits and surely will receive a cordial welcome whenever he chooses to revisit the Thorndike, whose destiny he guided for over twenty years.

And now on Dr Minot's retirement there comes a new director, William Bosworth Castle, Professor of Medicine, Master of Science (hon), as rugged an individualist as ever trod the floors of that mecca of individualists—the Thorndike Memorial Laboratory, Boston City Hospital. Yet new is hardly an apt word, for twenty-three years ago, when the Thorndike was still in its childhood, Big Bill was resident physician pursuing there the type of research that he is now directing.

Trained as a physiologist he thinks in terms of physiology and thinks with almost frightening clarity. Dr Castle's second outstanding quality—

unswerving integrity and honesty not only with others but also with himself—is scarcely less impressive than the first. The world knows him as a great investigator, but the men on "Two" and "Four"—the Second and Fourth Medical Services—know that, to boot, he is a very shrewd clinician. What is more important, he is a truly great and very unassuming man.

This, then, is the new director of the Thorndike Memorial Laboratory, and director of the Second and Fourth Medical Services of the Boston City Hospital. Under his guidance and with the continued help of the powers-that-be the Thorndike will continue to flourish and through clinical investigation the public will continue to be adequately served. This is as it should be.

### THE VAGINAL SMEAR AS A SCREENING TEST

Discussions of the periodic examination of apparently healthy people usually generate more heat than light. Before there will be real enthusiasm for applying a technic to broad segments of the population much more investigation is needed to determine the really essential elements of such examinations. We must know which procedures will be economically justified by the proportion of positive results when applied to large populations of varying sex, age and economic status.

The vaginal smear has been acclaimed in both the medical and the popular press as a most valuable adjunct in the diagnosis of uterine cancer. Since cervical cancer discovered early is often amenable to treatment, it is extremely important to evaluate this test and to determine its proper place in the definitive periodic examination that may be evolving.

Elsewhere in this issue of the *Journal* Lombard et al report promising preliminary results from a large series of vaginal smears made on patients in the Massachusetts cancer hospitals and state-aided cancer clinics. Final evaluation awaits further follow-up study. These investigators point out certain inaccuracies and drawbacks of the technic sufficient to suggest hesitation in accepting it as a routine measure applicable to the entire female

population of cancer-bearing age at present. Studies elsewhere have given similar results, though some are more enthusiastic than others.

There is need for further investigation to indicate best methods of obtaining specimens, selection of cases for the test, proportion of error that must be expected, cost of the examination and the most suitable administrative procedures. This type of report shows critical judgment and full appreciation of the really broad significance of screening tests for the detection of incipient disease among the general population.

### EFFECTS OF RUBELLA DURING PREGNANCY

LAST year Wesselhoeft<sup>1</sup> presented a very thorough review and discussion of the problems resulting from infection with German measles during pregnancy on the course of pregnancy and on the offspring. Aycock and Ingalls<sup>2</sup> also recently reviewed the subject of rubella, with particular reference to the problem of maternal disease as a principle in the epidemiology of congenital anomalies. At a recent meeting of the Midwestern Section of the American Federation for Clinical Research, Abel and Van Dellen<sup>3</sup> presented the results of their own survey of the effects of German measles during pregnancy. Their findings in 84 offspring of 82 mothers corroborated those of many authors quoted in the reviews mentioned above.

Three stillbirths were recorded from mothers having German measles during the first trimester of pregnancy. Twenty-five of the children were normal at birth. In seven of these the mother contracted the disease during the first trimester, eleven during the second and seven in the last. Fifty-six of the infants were abnormal at birth, thirty-six with a single defect and twenty with more than one defect. In forty-four (76 per cent) of these, the mother told of having German measles during the first trimester of pregnancy, eight in the second, one in the third and unknown in three. Nineteen of the infants had congenital heart disease, seventeen had cataracts, fourteen were deaf, and seven were mentally deficient. Gastrointestinal, eye, spinal and skeletal abnormalities also occurred in lesser numbers.

The most serious defects or combination of defects occur in women having German measles during the first trimester; defects are less serious and more infrequent in the second. In all, 87 per cent of the babies born of mothers having German measles during the first trimester were abnormal. No abnormalities developed in the third trimester.

Of particular interest is the manner in which these data were accumulated. One of the authors is a regular contributor to one of the popular syndicated health columns, which undoubtedly reaches millions of newspaper readers daily. This column was used as a medium for obtaining the information presented. He included a request for letters from mothers who had had German measles during pregnancy. They were asked to state the exact month of gestation in which the illness occurred and the effect on the offspring. Over 90 replies were thus obtained, and of these 82 were considered acceptable. The series includes two sets of twins, making a total of 84 children.

This method in reputable and critical hands undoubtedly opens up considerable possibilities for epidemiologic studies. The errors involved, however, are likely to be enormously greater than those obtained in studies of hospital histories or those based on personal surveys and interviews. It does, nevertheless, look like a very fertile field for obtaining at least a first approximation in many types of epidemiologic surveys.

### PLANNED PARENTHOOD REFERENDUM

FINAL petitions asking that the planned-parent-hood question be placed on the November ballots in Massachusetts have been filed with the secretary of state of the Commonwealth. The 8429 signatures to these petitions, added to those obtained in 1947, make a total of 88,659. Numbered among the supporters of the thesis that physicians should be permitted to give contraceptive aid to married women for the protection of life or health, the Planned Parenthood League of Massachusetts claims 3363 Massachusetts physicians, or a majority of the resident members of the Massachusetts Medical Society.

In 1947 a bill providing for legalization of the contraceptive measure was initiated on a petition of 80,230 voters. After hearings before the Public Health Committee, this bill failed to pass either house.

Forty-six states of the Union now permit contraceptive advice to be given by physicians to married women for the protection of life or health.

## MASSACHUSETTS MEDICAL SOCIETY

### DEATHS

**CAPELES** — Thomas F. Capeles, M.D., of Haverhill, died on August 12. He was in his sixty-fourth year.

Dr. Capeles received his degree from Tufts College Medical School in 1909. He was a member of the New England Ophthalmological Society and a fellow of the American College of Surgeons and the American Medical Association.

A brother survives.

**CARROLL** — Henry G. Carroll, M.D., of Salem, died on August 11. He was in his sixty-fifth year.

Dr. Carroll received his degree from Dartmouth Medical School in 1907. He was a member of the New England Ophthalmological Society and a fellow of the American College of Surgeons and the American Medical Association.

His widow, two sons, a daughter and a sister survive.

**GRAINGER** — Edward J. Grainger, M.D., of Winthrop, died on July 25. He was in his seventy-first year.

Dr. Grainger received his degree from Harvard Medical School in 1903. He was formerly vice-president on the staff of the Winthrop Community Hospital.

His widow, two brothers and a half-sister survive.

**MARSH** — Arthur W. Marsh, M.D., of Worcester, died on June 24. He was in his eighty-second year.

Dr. Marsh received his degree from Harvard Medical School in 1895. He was a former president of Worcester District Medical Society, a member of the New England Surgical Society and a fellow of the American College of Surgeons and the American Medical Association.

His widow, two daughters, a brother and four grandchildren survive.

## NEW HAMPSHIRE MEDICAL SOCIETY

### DEATH

**ELKAVICH** — Frank D. Elkavich, M.D., of Troy, died on July 27. He was in his fortieth year.

Dr. Elkavich received his degree from McGill University Faculty of Medicine in 1937. He was an associate staff member of the Elliot Community Hospital in Keene and a former president of the Cheshire County Medical Society. He was a fellow of the American Medical Association.

His widow, a son, a daughter, his parents, a brother and two sisters survive.

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### WOOD-TICK STUDY

The Massachusetts Department of Public Health is making a study of the wood-tick problem in the Commonwealth during the present season. This study was authorized by Chapter 36 of the Resolves of 1948.

The prevalence of ticks was rapidly declining by July 1, when the funds became available. Therefore, the most important part of the study this year is a survey to determine their geographical distribution. Much of the information, which is being collected on a questionnaire, is being supplemented by the identification of the ticks sent in by interested persons and of those collected by the personnel employed on the project.

The Department is most interested in receiving information about the prevalence of ticks outside the counties of Barnstable, Plymouth, Bristol, Nantucket and Dukes.

The co-operation of physicians in filling out questionnaires will be greatly appreciated. All information and any specimens collected should be forwarded to the Division of Communicable Diseases, 8 Beacon Street, Boston 8.

## MISCELLANY

### ALVARENGA PRIZE

In recognition of his studies on sludged blood the College of Physicians of Philadelphia has awarded the Alvarenga Prize for this year to Melvin H. Knisely, M.D., of the University of Chicago.

The Alvarenga Prize was established by the will of Pedro Francisco da Costa Alvarenga, of Lisbon, Portugal, an associate fellow of the College of Physicians of Philadelphia, to be awarded annually by the College of Physicians on each anniversary of the death of the testator, July 14, 1883.

## BOOK REVIEWS

*Gastritis*. By Rudolf Schindler, M.D. 8°, cloth, 462 pp., with 96 plates. New York: Grune and Stratton, 1947. \$10.00.

This is a painstaking and thorough study of an interesting disease by a pioneer worker who has had a vast experience in over twenty-five hundred cases in the last twenty-eight years, and who has worked hard to establish this difficult disease on a sound, anatomic and clinical basis.

The gross and microscopical pathology is given in great detail (seventy-four pages) as a basis for the disease and for correlation with symptoms. Gastritis is classified as acute and chronic, and chronic gastritis is divided into superficial, atrophic and hypertrophic and gastritis in other diseases (tumors, ulcers, postoperative). The causes of chronic gastritis are varied and often unknown. The author does not believe that alcohol plays an important part. Gastritis was found in about 40 per cent of the patients gastroscopied for gastric symptoms.

It is interesting to compare the visible changes in the gastric mucosa described by Wolf and Wolff in their fistula patient after emotional upsets with the changes in acute superficial gastritis, but Schindler does not believe that chronic gastritis is due primarily to mental events.

There is great divergence of opinion about the symptoms of gastritis and about the importance of the disease. Some authors consider it one of the most important clinical conditions, and others a symptomless and insignificant disease. The symptoms described — epigastric pain, loss of appetite, nausea, vomiting, weight loss, weakness, anemia and bleeding — seem general in type and not diagnostic. There is nothing characteristic about the ordinary physical examination, gastric analysis or x-ray picture in the author's opinion, and diagnosis is based solely on gastroscopy at present. There is real difficulty in correlating the symptoms with the picture seen at gastroscopy, and the author says, "for a long time to come the clinical picture of chronic gastritis will be subject to discussion and controversy."

For treatment the author's advice is to get rid of the cause if one can be found — infections, tobacco, vitamin deficiency and so forth — and to give a bland diet such as that used for peptic ulcer with hydrochloric acid or enzymes and perhaps liver extract in the atrophic form. The author takes a rather gloomy view of operations on the stomach for peptic ulcer and the frequency of postoperative gastritis and the difficulty of its treatment. The relation of gastritis to peptic ulcer, cancer and pernicious anemia is very fully described.

There are brief reports of 55 cases and nearly a hundred pages of photomicrographs. The color prints are clear and well chosen. The book is well written, illustrated and printed. It is a valuable contribution to this subject and is highly recommended to the internist and gastroenterologist.

*Textbook of Human Physiology*. By William F. Hamilton, Ph.D. 8° cloth, 504 pp. with 121 illustrations. Philadelphia: F. A. Davis Company, 1947. \$6.00.

The author makes it clear that the content of this book has been restricted to the things that the average medical student can encompass in the short time he is in the department of physiology. With this aim in view, much of importance has been left out in the hope that the clinic and the hospital will teach physiologic facts that the formal physiology course lacks the time to deal with. The author succeeds rather well in presenting the general outline of mechanisms whose normal or abnormal functioning is to be the central theme in the future life of the physician. There can be little doubt that the thirty-two chapters constitute merely the framework of physiology and that medical students will need to have their attention drawn to the urgent need for collateral reading. It seems to the reviewer that this textbook is more adapted for the use of college students than for that of medical students. Nevertheless, the book will serve a useful purpose in orientation in a course in human physiology.

*Diseases of the Joints and Rheumatism*. By Kenneth Stone, D.M. (Oxon), M.R.C.P. 8° cloth, 362 pp. with 58 illustrations. New York: Grune and Stratton, 1947. \$6.50.

This book contains much useful information about joints and about arthritis, but it fails to live up to its ambitious title. The classification of arthritis varies somewhat from that commonly employed, but it is logical and simple. The chapter on the physiology of joints is good. The author has an interesting theory in relating fibrositis and similar conditions to vagotonia. In future editions it is hoped that he will make a more complete discussion of symptoms and treatment of articular disease. The book is a useful but somewhat incomplete guide for the treatment of arthritis and allied conditions.

*Fatigue and Impairment in Man*. By S. Howard Bartley, Ph.D., and Eloise Chute, M.A. With a foreword by A. C. Ivy, Ph.D., M.D. First edition. 8° cloth, 429 pp. New York: McGraw-Hill Book Company, Incorporated, 1947. \$5.50.

The authors of this book are to be congratulated on a clearly written, comprehensive account of fatigue and impairment in man. The thesis is developed that very little of the work that has been done on fatigue refers to the experience of feeling tired and that fatigue is necessarily a reaction of the total organism. It is pointed out that the earliest studies dealing with impairment, work output and overt behavior have thrown light on fatigue merely in revealing what it is not, and in such approaches to the problem, considerations of bodily sensations, attitudes and matters of motivation have been almost totally neglected. No clear-cut distinction between fatigue and impairment has ever been made and constantly maintained.

Impairment is seen as referring to the condition of tissue, which is directly discovered only by physiologic and biochemical analysis, whereas fatigue is seen as an expression of the organization of the whole organism, which can be described only in personalistic terms. It is pointed out that fatigue is not an entity specified in quantitative units. The plan of the book is dictated by the distinction between fatigue and impairment, and after a chapter devoted to a detailed discussion of the various views on fatigue, electrophysiologic studies, anoxemia, lack of sugar, temperature

extremes and water-salt lacks, metabolism, hours and conditions of work in industries, drug action, neuromuscular activity, sleep, mental fatigue, personal factors in work situation, visual performance, conflict and frustration and chronic fatigue are considered. Each chapter is accompanied by many references and at the end of the book appears a valuable list of visual aids.

This book unquestionably represents a fundamental contribution to the important subject of fatigue and impairment in man.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Bergey's Manual of Determinative Bacteriology*. By Robert S. Breed, New York State Experiment Station (Cornell University), Geneva, New York; E. G. D. Murray, McGill University, Montreal; and A. Parker Hitchens, University of Pennsylvania, Philadelphia. Sixth edition. 8° cloth, 1529 pp. Baltimore: The Williams and Wilkins Company, 1948. \$15.00.

This standard reference work, first published in 1923 and last revised in 1939, has been completely revised and reset in a double column format for the sixth edition. The type content has been increased about 20 per cent. The work is supervised by a new board of editors, with Robert S. Breed of the original board of chairmen assisted by a group of sixty contributors. Some changes have been made in the outline classification. The number of species of fission fungi has been increased from 1335 in the previous edition to 1630 in the present edition. There is a new source and habitat index. Many new binomials have been included in the index of names of genera and species. The preliminary text comprises a historical survey of classifications of bacteria, how bacteria are named and identified and rules of nomenclature. The descriptions of bacteria are then presented by orders, suborders and families. The two indexes mentioned above conclude the text. The printing is well done with a good type on a good light paper. The weight of the book is not excessive for its size. The work is an essential reference book for all medical and public libraries and for all bacteriologists.

*Life: Its nature and origin*. By Jerome Alexander. 8° cloth, 291 pp. New York: Reinhold Publishing Corporation, 1948. \$5.00.

This monograph has been written primarily for the general reader and each topic is treated in as simple and elementary a manner as possible. The fundamental objective of the work is to show that life is dominated by catalysis. In order are discussed the origin and physical basis of life, the nature of living units, the catalytic mechanism whereby life exists, persists and proceeds, immunology, genetics, evolution and embryology. There are special chapters on some catalytic aspects of disease and drugs and on philosophy, the guide to mental health. Each chapter has a list of references mentioned in the text. Author and subject indexes conclude the book. The text is well written and arranged and the book is well published in every way. The volume should be in all large medical and general libraries.

*Occupational Medicine and Industrial Hygiene*. By Rutherford T. Johnstone, M.D., consultant in industrial health, and lecturer at the University of California, Los Angeles. 8° cloth, 604 pp., with 117 illustrations. St. Louis: The C. V. Mosby Company, 1948. \$10.00.

This new work on occupational medicine has been divided into four parts. The first comprises general topics, including workmen's compensation, medicolegal aspects, functions of the industrial physician, teaching of industrial medicine, diagnosis and laboratory procedures in diagnosis. The second and third parts and a portion of the fourth discuss the substances used in industrial plants — the solvents, metal and dust — and their hygienic and pathologic aspects. There are special

chapters on tuberculosis and pneumonia in industry, the dermatoses, synthetics and special industrial processes. Industrial hygiene in general is dealt with in two chapters, and the final chapter concerns pre-employment examinations and placement. The appendixes list the chemicals in common trade-name products and organic solvents used for cleaning or degreasing. A good index concludes the volume. Pertinent references are appended to each chapter. The material is well organized, and the text well written. The publishing is excellent. The work is recommended for all medical and public-health libraries and to industrial physicians.

*Pathological Histology*. By Robertson F. Ogilvie, M.D., F.R.C.P. (Edin.), F.R.S.E., lecturer in pathology and assistant in forensic medicine, University of Edinburgh, senior pathologist, Royal Infirmary, Edinburgh, pathologist to the Leith and Deaconess Hospitals, Edinburgh, and examiner in pathology and forensic medicine for the triple qualification. With a foreword by A. Murray Drennan, M.D., F.R.C.P. (Edin.), F.R.S.F., professor of pathology, University of Edinburgh. Third edition 8°, cloth, 459 pp., with 260 photomicrographs in color. Baltimore: The Williams and Wilkins Company, 1947. \$10.00.

This third edition of an English textbook, first published in 1940, has been extensively rewritten, revised and amplified. Fifteen subjects and plates have been added. The volume is designed for the use of students and as a companion to a standard textbook on pathology. A good index concludes the volume. The text is well printed with a good type on good light paper, with the color plates as inserts, making the book not too heavy for its size. The color work is excellent. The printing was done in Great Britain, and the binding in the United States. The volume should prove valuable as a reference work in all medical libraries.

*History of Medicine. A correlative text, arranged according to subjects*. By Cecelia C. Mettler, Ed.D., A.M., Ph.D. Edited by Fred A. Mettler, A.M., M.D., Ph.D., associate professor of anatomy, College of Physicians and Surgeons, Columbia University. 8°, cloth, 1215 pp. Philadelphia: Blakiston Company, 1947. \$8.50.

Dr. Mettler, in this new book on the history of medicine, has divided her subject into large, well recognized medical specialties and further subdivided them into chronologic periods within the subjects. The subjects covered comprise anatomy and physiology, pharmacology, pathology and bacteriology, physical diagnosis, medicine, neurology and psychiatry, venereology, dermatology, pediatrics, surgery, obstetrics and gynecology, ophthalmology and otology, and rhinology. The period covered is from the time of primitive man to the nineteenth century. Such important subjects as dentistry, veterinary medicine and public health are omitted. The modern period is considered as the seventeenth to nineteenth centuries. The treatment by subjects deprives the scholar of the broad perspective of a period in all branches of medicine, but as this approach may be found in the histories of Baas, Garrison and others, the new style of Dr. Mettler provides a reference work of outstanding value. Throughout the text extensive quotations are given from fundamental writings of various authors. In the section under medicine, entitled "Background of Early American Medicine," foreign names predominate to such an extent that it is very difficult to get a picture of American medicine of the eighteenth century. At least the two earliest medical books printed in the United States in Boston in 1708 and 1720, the *English Physician* and the *Pharmacopoeia* of Nicolas Culpeper should have been noted. The text is well written and well printed in two columns on a coated paper too heavy for this type of book. The printing of personal names in heavy type is to be commended as good practice. A long list of selected readings is appended to each chapter. The volume concludes with comprehensive indexes of authors and subjects. Valuable historical maps are printed on the lining papers of the binding. This is a bad practice, since such printings are liable to defacement and destruction. This work is recommended as a reference source to all medical and general libraries and to all physicians interested in the history of medicine.

*Symposium on Medicolegal Problems Under the co-sponsorship of the Institute of Medicine of Chicago and the Chicago Bar Association*. Edited by Samuel A. Levinson, M.D., Ph.D., University of Illinois College of Medicine for The Committees of the Institute of Medicine and The Chicago Bar Association. 12°, cloth, 255 pp. Philadelphia: J. B. Lippincott Company, 1948. \$5.00.

The papers in this small volume were read and discussed at joint meetings by fourteen legal and medical authorities (including Professor Alan R. Moritz, of the Harvard Medical School) held at Chicago in 1945. The program was arranged by representative committees of the Institute of Medicine of Chicago and the Chicago Bar Association. The meetings were attended by physicians, lawyers, social workers, hospital managers, industrial commissioners, theologians and interested lay people. The subjects selected for discussion were the medical witness in court and expert testimony, artificial insemination and its medicolegal implications, the practice of pathology and its medicolegal problems, operations to produce sterility, medicolegal implications, trauma and tumors in industrial medicine, and scientific tests in evidence, including blood-grouping tests in disputed-paternity cases and chemical tests for intoxication. A physician and a lawyer, specialists in their particular fields, discussed each topic, the physician presenting the current medical opinion, and the lawyer interpreting the law. The discussions participated in by the group and audience were long, pertinent and instructive. Dr. Hawkinson, speaking on the medical witness and expert testimony, reviewed the history of attempts to regulate testimony, including the state plans, in which was mentioned the Massachusetts Briggs Law and the Minnesota plan of supervising and regulating medical testimony in the Minnesota courts, a joint plan of the State Medical Association and the State Bar Association. On the question of artificial insemination, with its medical, legal, social and religious problems, it was brought out that the law at present is at variance with scientific advance and that there is no law covering the whole problem. In the discussion of the practice of pathology, the question of various privileges claimed by physicians and the physician-patient relation were presented medically and legally. Also, an interpretation of the laws governing the human dead body was given. The Municipal Court of the City of Chicago, as early as 1922, was interested seriously in the problem of eugenic sterilization. In the discussion on this subject it was pointed out that the legal proof should guide the physician although he is convinced that there is sufficient scientific evidence to justify this type of operation. The consensus of medical opinion is that a single trauma does not produce tumors. The courts have held that, since the cause of tumors is unknown, trauma may be one of the unknown factors leading to tumor formation. The burden of proof rests on the scientist. The objective of the symposium was to bring into the open questions confronting the medical and legal professions. The meetings were very successful and a second series was held in 1947, it is hoped to make the meetings an annual affair. The text is well written in a simple style. The volume is well published in every way. The seemingly high price for a small volume is justified by the probable anticipated limited distribution. The book is recommended for all medical and legal libraries and to all persons interested in medicolegal problems.

*The Rh Factor in the Clinic and the Laboratory*. Edited by Joseph M. Hill, M.D., and William Dameshek, M.D. 4°, cloth, 192 pp., with illustrations and tables. New York: Grune and Stratton, 1948. \$4.25.

This monograph is the joint work of fifteen authorities in their particular fields. The first article is a survey of the significance of the Rh factor, and is followed by articles on the various aspects of the Rh factor in clinical medicine. The last article is a historical review of Mexican blood transfusion. The book is well published in every way and should be in all medical libraries.

*Laboratory Technique in Biology and Medicine*. By E. V. Cowdry, professor of anatomy, Washington University, and director of research, The Barnard Free Skin and Cancer Hospital, St. Louis. Second edition 8°, cloth, 269 pp. Baltimore: The Williams and Wilkins Company, 1948. \$4.00.

The first edition of this manual was published in 1943 under the title, *Microscopic Technique*. The second edition has been revised to include methods developed since 1943. The

material is arranged alphabetically by subjects and printed in two columns to conserve space and paper. The volume should prove valuable as a ready reference source for all medical libraries and physicians and technicians.

*Modern Treatment of Peptic Ulcer* By Asher Winkelstein, M.D., associate physician for gastroenterology and physician in charge of the Gastro-Intestinal Clinic, The Mount Sinai Hospital, New York City, and assistant professor of clinical medicine (gastroenterology), Columbia University, College of Physicians and Surgeons. 8°, cloth, 201 pp. New York: Oxford University Press, 1948. \$4.00.

This small work considers the various aspects of the treatment of peptic ulcer. Etiology, pathology and prophylaxis are discussed, and ten chapters are devoted to drip therapy. There are chapters on vagotomy, therapy with enterogastrome, urogastrome and the protein hyperalimentation therapy, followed by consideration of the psychosomatic aspects. A bibliography and index conclude the volume. The publishing is well done in every way. The book should prove of value to physicians interested in the subject.

*Oxford Loose-Leaf Medicine* (Sixteen reprints from the Supplements) 4°, paper. New York: Oxford University Press, 1947. Available only to subscribers to complete sets of *Oxford Loose-Leaf Medicine*.

In 1947 the *Oxford Loose-Leaf Medicine* was amplified by the publication of a large number of revisions of various articles that were issued. Sixteen of these articles have been reprinted as separate publications. This material is available only to subscribers to complete sets of the work. Notable among these reprints may be mentioned Bright's disease, by Henry A. Christian, headache, by Walter C. Alvarez, arterial hypertension, by David A. Man and scarlet fever, by James D. Trask and Paul L. Boissert. The publication is well done in the usual excellent style of the Oxford University Press.

*Introduction to the History of Science*. Vol. III. *Science and Learning in the Fourteenth Century*. By George Sarton, D.Sc., L.H.D., and L.L.D., professor of the history of science, Harvard University, and associate in the history of science, Carnegie Institute of Washington. In two parts. 4°, cloth, 1018 pp. Baltimore: Published for the Carnegie Institute of Washington by Williams and Wilkins Company, 1947. \$20.00.

Dr Sarton in the third volume of his monumental work on the history of science, covers the period of the fourteenth century. In the earlier sections the literature and learning from the time of Homer through the thirteenth century were presented in three large volumes. These early volumes, published in 1927 and 1931 and long out of print, have recently been reprinted by a photographic process and are now available at reasonable prices. This volume, comprising 2155 pages, has been issued in two large volumes, dividing the century into two equal parts. In the preface by the author there are noted corrections to Volume I and addenda to Volumes I and II. The style of the work has been maintained as originally planned. The general chapters preceding each half century — a survey of science and intellectual progress, religious background, the translators, education and the philosophical and cultural background — are intended for consecutive reading. The special chapters on each field of knowledge are intended for reference purposes. The sections on medicine comprise one hundred and sixty-one pages. Appended to each author considered are references to his works by recognized authorities. A complete table of contents for the century precedes the text. An addenda of forty-two pages, made necessary by the long time required for printing, and a general bibliography of forty-one pages conclude the text. A comprehensive general index of names and subjects of 174 pages, and special Greek, Chinese and Japanese indexes conclude the volume. The publishing is well done in every way. Dr Sarton has spent the best part of his life in producing this scholarly and outstanding reference work that is practically impossible to review textually without writing another book. The complete set should be in all libraries, public and private, general and special. It is recommended for all medical libraries. It is hoped that Dr Sarton will be able to continue his studies through the fifteenth century where the literature is tremendous in quantity and will live to see them published as the crowning achievement of his life.

*Clinical Laboratory Methods and Diagnosis: A textbook on laboratory procedures with their interpretation*. By R. B. H. Gradwohl, M.D., D.Sc., F.R.S.T.M. & H. (London), director to the Gradwohl Laboratories and Gradwohl School of Laboratory Technic, pathologist to Christian Hospital, and director, Research Laboratory, St. Louis Metropolitan Police Department, St. Louis. Fourth edition. In three volumes. 4°, cloth. Vol. I, 1296 pp., 362 illustrations and 41 color plates. Vol. II, 1114 pp., 328 illustrations and 9 color plates. Vol. III, *Parasitology and Tropical Medicine*. By R. B. H. Gradwohl, and Dr. Pedro Kouri, director, Institute of Tropical Medicine, professor of parasitology and tropical medicine, vice-dean of the Faculty of Medicine, Havana University, and director of Laboratorios Kuha, Havana. 864 pp., 420 illustrations and 7 color plates. St. Louis: The C. V. Mosby Company, 1948. \$40.00 for the set.

This authoritative reference set has been greatly expanded over the previous edition of 1943, and contains 55 per cent more text material and 51 per cent more illustrative material. The revisions and expansions are so numerous that they cannot be listed in detail. A chapter on electrocardiography has been added, and the section on parasitology has been expanded from 394 to 819 pages and made a separate volume on parasitology and tropical medicine. References to the literature are printed as footnotes in their proper places. Volumes I and II, on clinical methods and diagnosis, are pagged consecutively, with a comprehensive index at the end of the second volume. Volume III is pagged separately and has its own index. The material is well arranged, and the typography, paper, illustrations and color work are excellent. The work is exceptional and should be in all medical libraries as an essential reference source.

## NOTICES

### ANNOUNCEMENTS

Dr W. Charles Inman, assistant commissioner, Massachusetts Department of Mental Health, has been appointed superintendent of the Grafton State Hospital, North Grafton, Massachusetts. He will assume the duties of that position on September 16.

Drs Leland S. McKittick, John B. McKittick and Thomas S. Risley announce the removal of their offices to 1180 Beacon Street, Brookline.

Dr William F. Ryan announces the opening of his office for the practice of ophthalmology at 520 Commonwealth Avenue, Boston.

### RESIDENCIES IN PSYCHIATRY AND NEUROLOGY

The Veterans Administration has immediate openings for at least a hundred young doctors interested in taking residency training in psychiatry or neurology, or both, it was recently announced.

Veterans Administration hospitals offering these residencies are situated in almost every section of the country. All are under supervision of the deans' committees, mostly composed of members of university faculties of Class A medical schools.

Applicants for residency training in these fields must be citizens of the United States and graduates of a school of medicine approved by the Veterans Administration and the Council on Medical Education and Hospitals of the American Medical Association, and must have completed an internship acceptable to the Veterans Administration.

In general, these residencies cover a three-year program of specialty training, although one-year and two-year programs are also available at most of the hospitals.

Junior or first-year residents must have completed a satisfactory internship and must be considered ready for specialization. Intermediate or second-year residents must have

the qualifications of a junior resident in addition to the equivalent of one year's training in the specialty. Senior residents must have the qualifications of a junior resident in addition to two years' training in the specialty.

Interested doctors may obtain information and application forms regarding the residencies by writing to the chief medical director, Veterans Administration, Washington 25, D C.

Residency selection and residency grades for the applicant are recommended by the dean's committee supervising the program at the Veterans Administration hospital in which the applicant desires to train.

#### VETERANS ADMINISTRATION RESIDENCY-TRAINING PROGRAM IN NEUROPSYCHIATRY

A limited number of openings are available for appointment to the residency-training program in neuropsychiatry of the Veterans Administration Department of Medicine and Surgery. This program is under the jurisdiction of the deans of the Boston medical schools (Harvard, Tufts and Boston University). Training in this program, which may be from one to three years, is given at

Cushing Veterans Administration Hospital, Framingham, Massachusetts

Bedford Veterans Administration Hospital, Bedford, Massachusetts

The Mental Hygiene Clinic of the Boston Regional Office, Veterans Administration, Boston, Massachusetts

West Roxbury Veterans Administration Hospital, West Roxbury, Massachusetts

White River Junction Veterans Administration Hospital, White River Junction, Vermont

Emphasis in the entire program is on psychiatry, with dynamic orientation, and includes closed ward, open ward, outpatient, child psychiatry and neurology.

Further information may be obtained from the chief neuropsychiatrist, Veterans Administration, Branch Office No 1, 55 Tremont Street, Boston 8, Massachusetts.

#### JOHN AND MARY MARKLE FOUNDATION GRANTS

Medical schools in the United States and Canada are invited by the John and Mary R. Markle Foundation to make nominations for the second group of scholars in medical science on or before December 1, 1948. Each school, through the dean, may nominate one candidate. No nominations from individuals will be considered.

The program is designed to aid promising young men and women, planning careers in academic medicine, who have not yet made their reputations. They should have completed the usual fellowship training in some area of science related to medicine and should hold, or expect to hold, in the academic year 1949-1950 a full-time faculty appointment on the staff of a medical school.

Grants of \$25,000, payable at the rate of \$5,000 annually, will be made to the schools over a five-year period for the support of each scholar finally selected or his research, or both.

The number of scholars to be appointed in 1949 has not yet been determined. Sixteen were chosen in 1948. A new booklet describing the plan is available on request from the Foundation, 14 Wall Street, New York 5, New York.

#### INTERNSHIPS IN VETERANS ADMINISTRATION HOSPITALS

A limited number of internships in Veterans Administration hospitals will be offered qualified medical graduates. The internships will be limited to the seventy-five Veterans Administration hospitals now offering residency-training programs in co-operation with fifty-nine Class "A" medical schools over the country. They will be further limited to hospitals that have bachelor quarters available on the station grounds. A survey is in progress to determine what housing is available.

The two types of internship that will be available are as follows "straight," for surgery, general medicine and other "straight" subjects, and "rotating," in which interns study under a rotating schedule, surgery, general medicine and related subjects. Arrangements will be made for affiliated training for obstetrics and pediatrics in other than Veterans Administration hospitals. Such affiliated training may not involve more than 20 per cent of a year. The hospital at which the affiliated training is obtained must be approved for internship by the Council on Medical Education and Hospitals of the American Medical Association.

"Mixed" internships will not be offered.

Internships will be for one year, subject to reappointment for one year, if the reappointment is desired and recommended by the local dean's committee. The dean's committee, composed of members of university faculties or prominent local doctors, supervise the residency training program and will also supervise internship training.

Annual pay for interns will not exceed \$1,800 a year. Quarters, subsistence and laundry will be furnished. The stipend at each hospital will be determined by the Veterans Administration's chief medical director on recommendations of the deans' committees and in conformance with the existing scale of remuneration for interns in the locality.

Interns will be appointed in accordance with the national policy for all medical schools and hospitals, once each year on November 15, their tour of duty to begin the following July 1 or January 1 following July 1.

The new program is under the supervision of Dr. Paul B. Magnuson, chief medical director of the Veterans Administration, and Dr. Edward Harvey Cushing, assistant medical director for research and education in the Department of Medicine and Surgery, Veterans Administration. Those interested in residency training or internship should make application to the dean's committee at the university co-operating with Veterans Administration in the program, or to the manager of the hospital in the area in which they prefer to serve.

#### SILIFORM AMPOULES

Druggists and the medical profession are urged by the Food and Drug Administration, Federal Security Agency, to return all stocks of Siliform ampoules to the manufacturer, The Heilkraft Medical Company, Boston, Massachusetts. This injection drug, which should be sterile, is potentially dangerous since samples collected on the market contain living organisms. Siliform is injected by some physicians and osteopaths in the belief that it will relieve patients suffering with rheumatism as claimed by the manufacturer. The Food and Drug Administration found the contaminated samples after a routine inspection at the Heilkraft factory disclosed that the Siliform ampoules had been manufactured without sterilization. Intensive recall efforts by the manufacturer and the Food and Drug Administration since July 15 have not brought in all of the contaminated stocks. The article, which moves slowly, was shipped to 37 states from Maine to California and later was redistributed by wholesalers who cannot trace many of their sales. Some going back as far as 1946 have been found on the market. These ampoules may be in the hands of doctors, hospitals, clinics and retail and wholesale druggists.

#### SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, SEPTEMBER 2

FRIDAY SEPTEMBER 3

\*10:00 a.m.-12:00 p.m. Medical Staff Rounds. Peter Bent Brigham Hospital.

TUESDAY SEPTEMBER 7

\*12:15-1:15 p.m. Chnicroontgenological Conference. Peter Bent Brigham Hospital.

\*1:30-2:30 p.m. Pediatric Rounds. Burnham Memorial Hospital for Children. Massachusetts General Hospital.

WEDNESDAY SEPTEMBER 8

\*12:00 p.m.-1:00 p.m. Clinical Conference. (Children's Hospital) Amphitheater. Peter Bent Brigham Hospital.

\*Open to the medical profession.

*At the Friday Night Social, Jeb Crowell had the whole audience in stitches—doing a take-off on the blustering cocksure character who belittles everybody and everything that isn't from his own home town*

Well, we can laugh at that sort of character because from where I sit, Americans are just the opposite. We like to boast a bit perhaps, about the paint job on the new barn, or the missus' style of cooking—but we aren't intolerant of people who don't think or act the same way we do.

*In our town, for instance. Some folks like band concerts, others don't—some families serve beer with dinner, others, buttermilk. As for politics, there's plenty of healthy disagreement.*

But when it comes to denying folks the right to think or act as they choose no, we're simply like you—we don't believe in it, whether it goes for serving beer, or speaking one's mind on public affairs

# BACKGROUND

The use of cow's milk, water and carbohydrate mixtures represents the one system of

infant feeding that consistently, for over three decades, has received universal pediatric

recognition. No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri-Maltose.

## THE ROLE OF SODIUM IN THE PRODUCTION OF EDEMA\*

JOHN P. PETERS, M.D.†

NEW HAVEN, CONNECTICUT

THE term "edema" is applied to swellings produced by excessive accumulation of extracellular fluid without definite bounding membranes. These may be local or general. They are usually, but not always, associated with expansion of the total extracellular fluid of the body. They are even more loosely correlated with the total amount of water in the body. The simplest example of the formation of edema without change of the volume of fluid in the body is the swelling of the feet of a subject who stands still or rests in a relaxed position against a board at an angle of 60°. It is of the utmost importance in the analysis of edema to distinguish between the influence of exchanges between the body and the external environment on the one hand, and the distribution of fluid within the body on the other.

Although the extracellular fluid is more or less continuous, the distribution of this fluid need not be uniform. Pools of edema may occur because of local disturbances of the forces that determine the formation and removal of extracellular fluid. For example, in lymphedema fluid containing a high concentration of protein accumulates in the lower extremities because the lymphatic vessels are obstructed. If the subject is placed in the recumbent position with feet elevated, the fluid seeps into the flanks, which may become temporarily edematous.

The principal components of the extracellular fluid are sodium salts, chiefly the chloride, and water. The proportions of these components, which can diffuse freely throughout the extracellular fluid, are sedulously preserved by means discussed below. The accumulation of edema is limited, therefore, by the supply of either salt or water.

Motions of fluid between the blood capillaries and the adjacent spaces are governed, as Starling<sup>1</sup> showed, by the balance between two opposing forces, hydrostatic pressure and colloid osmotic pressure. In the simplest concept of the principle, the force

driving fluid from the capillaries is the blood pressure in these vessels, the force driving or drawing water back into the blood stream is the osmotic pressure of the proteins, and especially albumin, which has a smaller molecular size than globulin. Such a simplified concept assumes that the fluid about the capillaries contains no protein and is under no hydrostatic pressure. Actually, this fluid does contain variable amounts of protein and is under a certain hydrostatic pressure, the elasticity of the tissues, or tissue tension. The equilibrium between blood and extracellular fluid is, therefore, more precisely defined as follows: transudation is favored by capillary blood pressure and colloid osmotic pressure of perivascular fluid and opposed by colloid osmotic pressure of plasma and by tissue tension, factors that contribute to tissue tension are inherent inelasticity of tissues and distention of tissues by fluid because of imbalance of capillary-tissue exchange and variations of lymphatic drainage.

It is thus evident that the tendency to transudation cannot be correlated directly with either capillary blood pressure or serum albumin alone. Nevertheless, the applicability of the Starling principle to the formation of edema in a variety of conditions has been challenged because the presence and magnitude of edema is not directly correlated with either or both of these forces. The validity of this theory does not rest upon physical measurements of capillary blood pressure and colloid osmotic pressure. It follows naturally from thermodynamic laws if the composition of extracellular fluid is identical with that of an ultrafiltrate of plasma, which has been demonstrated by abundant evidence. The brilliant experiments of Krogh, Landis and others proved that hydrostatic pressure and colloid osmotic pressure in particular systems of the body are susceptible to accurate measurement. With present knowledge it can be asserted that if these measurements had been incompatible with the Starling principle, it would have been a reflection upon the measurements, not the principle.

It is fundamental to a critical evaluation of the formation of edema that physiologic and clinical

\*Presented at a meeting of the Boston City Hospital House Officers Association, Boston, April 20, 1948.

†John Slade Eli Professor of Medicine, Yale University School of Medicine.

hypotheses dealing with this process be compatible with basic mathematical, physical and chemical laws. If the simple relation between the concentration of serum albumin and transudation from the blood stream appears to be violated, conditions of equilibrium must be more carefully examined. One reason for discrepancies is the fact that capillary blood pressure is not uniform throughout the blood stream. Its measurement in the intact animal in any part of the blood stream is difficult, in most parts it is impossible. It must never be confused with arterial pressure, with which it may even be inversely related under certain circum-

stances. It may be attributed to constant slight seepage through the capillary walls, possibly with contributions from the cells bathed by this fluid. This protein cannot return to the circulation through the intact capillary walls, but is taken up selectively by the lymphatic vessels. This explains the stubborn character of lymphatic edema and the high concentrations of protein found in such fluid. Unfortunately, neither the volume nor the flow of lymph can be measured.

In certain parts of the circulation, especially the liver and portal circulation, the vessels appear to be regularly and of necessity more permeable to protein.<sup>1, 2</sup> This was first demonstrated by Starling,<sup>1</sup> who recognized that the blood pressure in the portal vein is so low that if there were not protein in the fluid about the capillaries in this region the tissues would become completely desiccated. There must be in these regions a continuous circulation of protein from blood stream to extracellular fluid and back through the lymphatic vessels and the thoracic duct to the blood stream. This has been demonstrated by means of foreign proteins and various materials that adhere to or combine with protein.

Among these materials are the dyes, including Evans blue (T-1824), employed for the measurement of circulating plasma volume.<sup>3</sup> These dyes are retained in the blood stream, not by their molecular size, but because they combine with albumin. Within five minutes of its injection into the blood stream Evans blue can be detected in high concentration in thoracic-duct lymph.<sup>4, 5</sup> This being true, no refinement of colorimetric techniques and no mathematical manipulations can make it an accurate measure of the circulating plasma. Always it must measure, in addition to the circulating plasma, part of the extracellular fluid into which it penetrates. If the volume of this extra circuit were constant and proportional to that of the circulating blood, and if the proportion of protein to water in it bore a constant relation to those in the plasma, the method might serve for the measurement of changes in plasma volume. But there is reason to believe that these factors are highly variable. If the protein and dye that escaped from the circulation were irrevocably lost, such a relative plasma volume could be estimated by mathematical extrapolation. But this system, so aptly devised for the well-being of the animal, was so damnably conceived to thwart the physiologist that part, and only a variable part, of the protein and dye is returned to the circulation again through the thoracic duct. The chief variables encountered in measurements of plasma volume by the dye method are as follows: those that are always operative include time of mixing and distribution in the blood stream, escape from the blood stream, return to the blood stream by lymph and permanent removal from plasma and lymph,

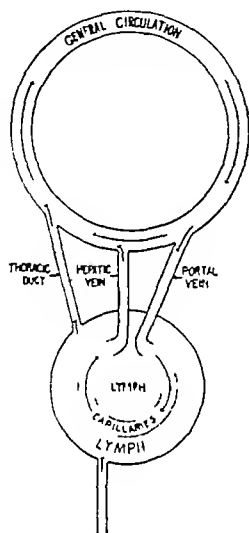

FIGURE 1 Schematic Representation of the Circulation  
The broken lines of the capillary walls in the portal circulation indicate that these vessels are permeable to protein

stances. It is more closely, but not precisely, related to venous pressure, which is notoriously subject to local variations. Although the colloid osmotic pressure of the blood plasma is relatively uniform throughout the blood stream, the colloid osmotic pressure and the hydrostatic pressure of the extracellular fluid are subject to local variations and are not everywhere susceptible to measurement. Finally, the Starling exchange is not the only means by which fluid can escape from the extracellular spaces, the lymph channels provide an alternate route. Drinker and others have shown that the flow of lymph in normal lymphatic vessels is accelerated whenever transudation from the capillaries increases. One of the forces responsible for this accelerated flow is presumably increased tissue pressure.

Normally, peripheral capillaries appear to be so impervious that extracellular fluid or subcutaneous edema fluid is almost free from protein. The small amounts of protein in normal extracellular fluid

those that are sometimes operative comprise variations of circulating blood volume during a test, variations of volume of the thoracic-duct lymph system (that part of the extracellular fluid, drained by the thoracic duct, into which the dye penetrates) and variations of flow of the thoracic-duct lymph during a test. Since all are uncontrollable and unmeasurable, it should be evident to reasoning persons that the method can have no real value. A rather naïve diagram (Fig 1) has been devised to illustrate this point in another way. The large circle above represents the general circulation, impervious to protein. Below is a shunt through the portal circulation, which contains a capillary bed, the broken outlines of which indicate that it is pervious to protein. This lies in a compartment representing the region drained by the thoracic duct. If the volume of the portal capillary bed merely expanded, without any increase of the total circulating fluid, the volume of plasma measured by the dye method would not change, although the amount of blood available to organs supplied by the general circulation would be reduced. If, when the portal capillary bed expanded, an equal volume of fluid entered the circulation, the volume of circulating plasma would increase, although only the usual amount would be available for organs in the general circulation. Thus far the dye method would give no misinformation about changes of circulating plasma volume. If, without any change of volume in the system, loss of protein and dye from the portal capillaries increased, the plasma volume by the dye method would seem to expand. This specious appearance of expansion would be greatly exaggerated if, at the same time, the thoracic-duct lymph compartment became larger.

In view of these considerations there should be no surprise that measurements by means of radioactive red blood cells or by carbon monoxide, which attaches itself to red blood cells, give smaller, and I should say more reasonable, values than dyes for changes of blood volume in pathologic or disturbed physiologic states.<sup>6,7</sup> Granted that red blood cells are not evenly distributed throughout the circulation, an unevenness that has, I believe, been grossly exaggerated, this will not correct the errors inherent in the dye methods. It merely invalidates the only alternative methods. These technical details have been discussed at length because a large body of physiologic and clinical theory dealing with circulatory disorders and fluid exchanges depends for its validity largely upon measurements of blood volume by dye methods.

The exchange of water between the extracellular fluid and the cells appears to be controlled almost entirely by the osmotic pressure of electrolytes in the extracellular fluid, which, in turn, depends mainly upon the concentration of sodium in the

fluid. This can be roughly symbolized by the equation

$$\frac{\text{Volume of E}}{\text{Volume of I}} \propto \frac{\text{Osmotic Pressure E}}{\text{Osmotic Pressure I}} \propto \frac{([Na] + [K])E}{([Na] + [K])I}$$

in which E and I represent extracellular and intracellular fluids respectively. The relative proportions of extracellular and intracellular fluid vary with the relative osmotic pressures of these fluids, which, in turn, depend upon the concentrations in the two mediums of those osmotically active components to which the cellular membranes are impervious. These are mainly sodium and potassium. The chief variable among these is the sodium of the extracellular fluid, which is, therefore, the principal determinant of the relative volume of the intracellular fluid. When the concentration of sodium falls the cells take up water and swell. When the concentration of sodium rises, the cells give up water and contract.

To form the 1000 to 1500 cc of urine ordinarily excreted by a normal person in a day, Smith<sup>4</sup> has estimated that about 180 liters of water must be filtered through the glomeruli in the course of twenty-four hours. With this fluid are filtered about 24,000 milliequivalents of sodium and 20,000 of chloride to yield 80 to 180 milliequivalents of sodium chloride in the urine. This means that more than 99 per cent of the water and a still larger proportion of the sodium and chloride from the glomerular filtrate must be reabsorbed in its passage down the tubules. This process of reabsorption is so regulated that reabsorption of sodium, chloride and water can be varied independently.

The various steps in this process of reabsorption have been partly elucidated by direct analyses of mammalian tubular fluid made by Walker et al.<sup>8</sup> in Richards's laboratory and by inferential evidence adduced by Shannon<sup>9</sup> and others. Attention will be centered on sodium salts and water. It need only be said about urea that its excretion is roughly proportional to filtration and requires a certain proportion of water. Reabsorption of water is therefore limited by the concentration of urea in the glomerular filtrate, which is, in turn, directly proportional to the rate of nitrogen metabolism and the concentration of urea in the blood. Sodium and chloride, on the other hand, can be almost or quite completely reabsorbed from the tubules.

The reabsorptive process is tentatively outlined in Table 1. As the 180 liters of isotonic glomerular filtrate pass through the proximal tubules, about 60 to 80 per cent of the water, all the glucose and fractions of other solutes are removed, together with a roughly equivalent amount of sodium and chloride. There remains an isotonic solution in which the ratio of sodium to chloride, originally about 1.3:1, has become 1:1—that is, the sodium bicarbonate has been reabsorbed, leaving prac-

tically all the remaining sodium as sodium chloride, together with the other solutes that will ultimately be found in the urine. In the loop of Henle a variable amount of sodium chloride is withdrawn. Obviously this is not withdrawn in solid form as the table suggests, but always in this step far more salt than water is reabsorbed. This leaves a hypotonic solution. Finally, in the terminal convoluted

The terminal reabsorption of water appears to be controlled chiefly by the antidiuretic principle of the posterior pituitary hormone, which Heller<sup>10</sup> has succeeded in separating from the pressor principle. The presence in the urine of antidiuretic principle has been demonstrated not only in states of dehydration in which there is need to conserve water but also in a variety of pathologic conditions

TABLE 1 *The Process of Reabsorption*

SITE OF ACTION	SOLUTION	VOLUME	SODIUM	CHLORIDE	RATIO OF SODIUM TO CHLORIDE	UREA NITROGEN
		<i>liters</i>	<i>mm</i>	<i>mm</i>		<i>gm.</i>
Glomerular filtrate	Isotonic	180.0	24,000	20,000	1.25:1	24
Proximal convoluted tubules	Isotonic	54.0	7,600	7,600	1:1	—
Loop of Henle	Hypotonic	54.0	140	140	1:1	—
Terminal convoluted tubules	Hypertonic	1.0	140	140	1:1	12

tubules water is abstracted to yield the fully elaborated urine, which is usually hypertonic.

If this description of the sequence of events is correct, sodium salts have a topographic priority over water in the process of reabsorption. Whether the sequence follows the order described or not, sodium salts have a functional priority over water and enjoy a greater degree of freedom. If an animal is deprived or depleted of sodium chloride these ions promptly disappear almost completely from the urine. The enormous quantities still provided to the tubules through the glomeruli are almost entirely reabsorbed. The administration of large amounts of water and procedures that alter the rate of glomerular filtration have no effect per se on the reabsorption of sodium chloride, although they may vary the volume of urine greatly. The terminal reabsorption of water, on the other hand, is limited by the quantity of solutes requiring excretion—that is, the quantity that escapes reabsorption in the proximal convoluted tubules and the loop of Henle. Among these are sodium salts. If, for any reason, these salts are not reabsorbed, the quantity of water that can be reabsorbed in the terminal process is proportionally reduced. Water, therefore, has an obligation to sodium salts that is not reciprocated. Moreover, water is similarly at the mercy of all solutes that find their way to the terminal segments of the tubules.

Since the reabsorption of both sodium salts and water involves the production of concentration gradients across the membranes of the tubular cells, these processes must require the expenditure of energy. If, therefore, the kidney is injured by disease, reabsorption of sodium chloride and water will diminish. In advanced renal insufficiency the ability of the kidneys to conserve both salt and water is impaired. This disability is manifested in polyuria. In this condition restriction of salt is contraindicated, it may even be advisable to give extra salt.

attended by edema, the nephrotic syndrome,<sup>11</sup> toxemias of pregnancy,<sup>12</sup> cirrhosis of the liver<sup>13</sup> and so forth. The obvious inference is that the oliguria of these conditions is partly or wholly induced through the influence of posterior pituitary activity. The obligation of water to sodium and the independent control of the two are illustrated by the action of the antidiuretic hormone. If this is given with a dose of water to an animal, the water will be almost entirely retained, though excretion of salt continues unchanged. If, on the other hand, the antidiuretic hormone is given with a dose of salt solution, it has little or no antidiuretic effect because the salt, which is not affected by the hormone, demands water for its excretion. Conversely, the administration of salt aggravates diabetes insipidus because the salt cannot be concentrated in the urine in the absence of the antidiuretic hormone.

The evidence concerning control of the reabsorption of sodium salts is less direct. Adrenalectomized animals and patients with Addison's disease tend to waste sodium in the urine. This wastage can be prevented by either cortical extract or desoxycorticosterone acetate. On the other hand, cortical extracts have no pronounced effect upon the excretion of salt by the intact animal. The reabsorption of sodium is increased by desoxycorticosterone acetate, but this is not a natural adrenal steroid. It is, moreover, impossible to demonstrate changes in adrenocortical activity that are related to salt excretion. Nevertheless, from inferential evidence it is tentatively proposed that reabsorption of sodium salts is governed by a steroid secreted by the adrenal cortex.

Regardless of the specific principle that controls reabsorption of sodium, the conditions that influence it may be examined. When the concentration of sodium salts in the serum alone is varied by administration of different quantities of these salts with adequate amounts of water, the excre-

tion of sodium varies directly with its concentration in the serum. Such a relation cannot, however, be discerned under normal dietary conditions and can be strikingly disturbed by certain procedures. The reabsorption of sodium is powerfully affected by factors other than its concentration in the serum. Among these factors is the state of hydration (or some function of the state of hydration) of the subject. If an animal is deprived of all water, some sodium may be immediately lost in the urine, but, after only a short interval, the excretion of both sodium and chloride falls to a minimum. This causes their concentrations in the serum and extracellular fluids to rise<sup>14, 15</sup>. The same phenomenon may be observed when animals are dehydrated by diuretic measures, such as injection of sodium sulfate without adequate amounts of water. This behavior has obvious beneficial effects by withdrawal of sodium chloride from the urine: the animal is enabled to excrete other solutes with a smaller expenditure of water, and the accumulation of sodium chloride in the extracellular fluids raises the osmotic pressure of these fluids, thereby causing water to emerge from the cells. This protects the extracellular fluid from extinction and provides additional water for the formation of urine. By this reaction the water loss is distributed throughout the whole water of the body.

The most powerful known stimulus to the reabsorption of sodium appears to be the need to conserve water. At first sight it seems illogical that this need should express itself primarily through an action on sodium rather than water. If, however, salt were not reabsorbed, the anti-diuretic hormone could not effectively limit the excretion of water. Moreover, the intracellular water would not be made available for the formation of urine.

Reabsorption of water—that is, activity of the antidiuretic hormone—appears to be promoted by an increase of the concentration of solutes, perhaps more specifically sodium salts, in the serum. This has been demonstrated directly by Verney<sup>16</sup>. It can also be inferred from the action of desoxycorticosterone acetate (Table 2). If this compound is injected into a normal animal that is given no water or only the usual amounts of water, serum sodium rises. At the same time the excretion of water is retarded. The consequence is an increase of the concentration of sodium and of the total amounts of sodium and water in the extracellular fluids. Apparently when the sodium of the serum rises the urine volume is reduced by action of the antidiuretic hormone, just as it is in dehydration. The increased concentration of sodium in the serum also has the effect of stimulating thirst. If, then, the animal has free access to water, it will drink enough to dilute the serum sodium to the normal concentration. This, in turn, inhibits antidiuretic activity. The actual effect of an excess of

desoxycorticosterone acetate, therefore, is to produce a state resembling diabetes insipidus. This differs, however, from posterior pituitary diabetes in several respects. In desoxycorticosterone diabetes insipidus the primary factor is thirst; in posterior pituitary diabetes insipidus it is polyuria. In the former the amounts of salt and water in the body are greater and in the postpituitary syndrome less, than normal. Although the desoxycorticosterone

TABLE 2 *Comparison of Findings in Two Types of Diabetes Insipidus*

POSTERIOR PITUITARY DIABETES	DESOXYCORTICOSTERONE DIABETES
Initial inhibition of reabsorption of water	Initial increase of reabsorption of sodium
Primary diuresis	Primary thirst
Deficient body water	Excess body water
Deficient body sodium	Excess body sodium

acetate syndrome is initiated by an increase in the amount of sodium in the body, so long as water is freely available the animal will drink enough water to keep the serum sodium normal or only slightly elevated. This point deserves emphasis: retention of sodium, if there is free access to water, because it stimulates thirst, is not associated with an excessive concentration of sodium in the serum. High serum sodium is almost invariably a sign of dehydration.

A patient with postpituitary diabetes, if deprived of water, will become dehydrated and will develop hypernatronemia and hyperchloremia. These disorders will be exaggerated if salt is given. This cannot easily be demonstrated in the clinic because withdrawal of water, especially if salt is given, is extremely distressing to such patients. We have recently encountered a striking example of this state. A young woman who had recently had a craniopharyngioma removed was admitted to the hospital because of headaches, dizziness, nausea, vomiting and confusion. Because of signs of increased intracranial pressure an exploration was immediately undertaken. A cyst, found in the third ventricle, was aspirated and removed. The patient withstood the operation surprisingly well. Besides a transfusion of 500 cc of blood she was given 1000 cc of physiologic saline solution and 1000 cc of 10 per cent glucose solution intravenously. The next morning her pulse was rapid and her blood pressure low, but she was conscious and did not appear to be in shock. On inquiry it was found that she had voided 3000 cc since the operation—more fluid than she had received, despite the dehydrating effect of the procedure and a moderate elevation of temperature. It was then discovered that her serum sodium, which had been 142 mm (upper limit of normal) before the operation, had risen to 171 mm, with chloride

tically all the remaining sodium as sodium chloride, together with the other solutes that will ultimately be found in the urine. In the loop of Henle a variable amount of sodium chloride is withdrawn. Obviously this is not withdrawn in solid form as the table suggests, but always in this step far more salt than water is reabsorbed. This leaves a hypotonic solution. Finally, in the terminal convoluted

The terminal reabsorption of water appears to be controlled chiefly by the antidiuretic principle of the posterior pituitary hormone, which Heller<sup>11</sup> has succeeded in separating from the pressor principle. The presence in the urine of antidiuretic principle has been demonstrated not only in states of dehydration in which there is need to conserve water but also in a variety of pathologic conditions

TABLE 1 *The Process of Reabsorption*

SITE OF ACTION	SOLUTION	VOLUME	SODIUM	CHLORIDE	RATIO OF SODIUM TO CHLORIDE	UREA NITROGEN
		<i>liters</i>	<i>mm</i>	<i>mm</i>		<i>gm</i>
Glomerular filtrate	Isotonic	180.0	24,000	20,000	1.25:1	24

Terminal convoluted tubules	Hypertonic	1.5	140	140	1:1	12

tubules water is abstracted to yield the fully elaborated urine, which is usually hypertonic.

If this description of the sequence of events is correct, sodium salts have a topographic priority over water in the process of reabsorption. Whether the sequence follows the order described or not, sodium salts have a functional priority over water and enjoy a greater degree of freedom. If an animal is deprived or depleted of sodium chloride these ions promptly disappear almost completely from the urine. The enormous quantities still provided to the tubules through the glomeruli are almost entirely reabsorbed. The administration of large amounts of water and procedures that alter the rate of glomerular filtration have no effect per se on the reabsorption of sodium chloride, although they may vary the volume of urine greatly. The terminal reabsorption of water, on the other hand, is limited by the quantity of solutes requiring excretion—that is, the quantity that escapes reabsorption in the proximal convoluted tubules and the loop of Henle. Among these are sodium salts. If, for any reason, these salts are not reabsorbed, the quantity of water that can be reabsorbed in the terminal process is proportionally reduced. Water, therefore, has an obligation to sodium salts that is not reciprocated. Moreover, water is similarly at the mercy of all solutes that find their way to the terminal segments of the tubules.

Since the reabsorption of both sodium salts and water involves the production of concentration gradients across the membranes of the tubular cells, these processes must require the expenditure of energy. If, therefore, the kidney is injured by disease, reabsorption of sodium chloride and water will diminish. In advanced renal insufficiency the ability of the kidneys to conserve both salt and water is impaired. This disability is manifested in polyuria. In this condition restriction of salt is contraindicated, it may even be advisable to give extra salt.

attended by edema, the nephrotic syndrome,<sup>11</sup> toxemias of pregnancy,<sup>12</sup> cirrhosis of the liver<sup>11</sup> and so forth. The obvious inference is that the oliguria of these conditions is partly or wholly induced through the influence of posterior pituitary activity. The obligation of water to sodium and the independent control of the two are illustrated by the action of the antidiuretic hormone. If this is given with a dose of water to an animal, the water will be almost entirely retained, though excretion of salt continues unchanged. If, on the other hand, the antidiuretic hormone is given with a dose of salt solution, it has little or no antidiuretic effect because the salt, which is not affected by the hormone, demands water for its excretion. Conversely, the administration of salt aggravates diabetes insipidus because the salt cannot be concentrated in the urine in the absence of the antidiuretic hormone.

The evidence concerning control of the reabsorption of sodium salts is less direct. Adrenalectomized animals and patients with Addison's disease tend to waste sodium in the urine. This wastage can be prevented by either cortical extract or desoxycorticosterone acetate. On the other hand, cortical extracts have no pronounced effect upon the excretion of salt by the intact animal. The reabsorption of sodium is increased by desoxycorticosterone acetate, but this is not a natural adrenal steroid. It is, moreover, impossible to demonstrate changes in adrenocortical activity that are related to salt excretion. Nevertheless, from inferential evidence it is tentatively proposed that reabsorption of sodium salts is governed by a steroid secreted by the adrenal cortex.

Regardless of the specific principle that controls reabsorption of sodium, the conditions that influence it may be examined. When the concentration of sodium salts in the serum alone is varied by administration of different quantities of these salts with adequate amounts of water, the excre-

rather than in the kidneys themselves but this will not alter the nature of the argument) The most crucial problem related to the formation of edema is the discovery of the criteria by which the kidneys determine whether to accelerate or retard the reabsorption of sodium

Obviously, accumulation of fluid in the extracellular compartment is a matter of indifference to the kidneys. If it were not, they would dehydrate all the rest of the body in behalf of a milk leg or a lymphedema. On the contrary, they will reabsorb salt and water for the sake of the patient at large while the edema is forming. In these conditions, if water and salt are not given, the blood volume diminishes as the edema accumulates. Presumably, the kidneys, finding that fluid is escaping from the circulation, conclude that there is need to conserve water and therefore respond by reabsorbing more than the usual quantity of sodium salts.

The edema that accompanies hypoalbuminemia, whether this is referable to plasmapheresis, nutritive deficiencies or albuminuria, appears to originate in a similar manner. The sequence of events in all these states is as follows: escape of fluid from the circulation, retention of sodium and chloride, and retention of water. In terms of renal physiologic mechanisms implemented by their appropriate agencies, these processes are expressed as follows: the development of a serum albumin deficit causes a reduction of colloid osmotic pressure that results in the escape of fluid from the circulation, reduction of the circulating blood volume accelerates the reabsorption of sodium salts (presumably through the influence of increased secretion of an adrenal cortical hormone), resulting in the accumulation of sodium salts in the serum, and increased concentration of sodium in the serum causes thirst and accelerates reabsorption of water through in-

edema but little, if at all, and by diluting the sodium salts in the extracellular fluid, it should inhibit the action of the antidiuretic hormone, permitting the water, but not the salt, to be excreted. Limitation of water, on the other hand, would have only a slight effect on the edema because it would increase the concentration of sodium salts in the serum, thereby stimulating antidiuretic activity. (Also, it would be a cruel measure because it would create intolerable thirst.) Administration of sodium salts

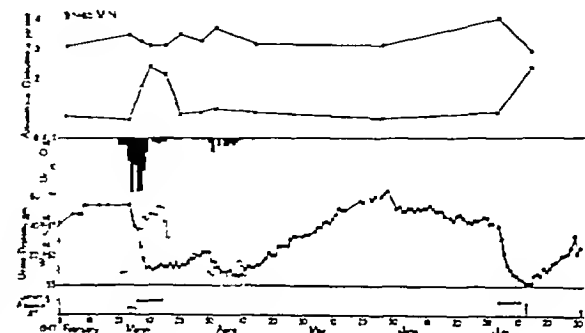

FIGURE 3 Effect of Human Serum Albumin Injections upon the Edema of a Patient with a Nephrotic Syndrome. Concentrations of albumin and globulin in the serum are shown in the top segment of the figure. The arrows in the lower segment indicate injections of salt-poor human serum albumin. (The serum albumin was furnished by the Administrator of the National Blood Program, American Red Cross, or recommendation of the Subcommittee on Blood and Blood Derivatives of the Red Cross Medical Advisory Committee.)

would conduce to edema because it would exaggerate the dehydration reaction, thus stimulating antidiuretic activity. Restriction of sodium salts would minimize the dehydration reaction and the stimulus to antidiuretic activity. The term "dehydration reaction" is applied to reabsorption of sodium by the kidneys to conserve water. Essentially, this describes the behavior of patients with edema of either nephrosis or heart failure.

If these phenomena were analyzed from the standpoint of exchanges of water and salt alone, the impression would be derived that the primary and initial reaction was retention of sodium, an impression that would gain additional support from the observation that mercurial drugs, which act by inhibiting the reabsorption of chloride, are effective diuretics in these forms of edema. The sequence that has been proposed is vividly illustrated by the effect of serum albumin in Figure 3. The patient, an eighteen-year-old girl in the nephrotic phase of a glomerular nephritis, had generalized edema that was resistant to salt restriction and the usual diuretic measures. Her serum albumin was less than 1 per cent. After a preliminary period of observation she was given daily intravenous injections of salt-poor human serum albumin, which

TABLE 4 Effect of Water and Salt on Edema

FACTOR	EFFECT ON SODIUM SALTS IN BODY	EFFECT ON ANTIDIURETIC ACTIVITY	EFFECT ON DEHYDRATION REACTION
Excess of water	Diluted	Inhibited	—
Limitation of water	Increased	Stimulated	—
Excess of sodium	Increased	Stimulated	Exaggerated
Limitation of sodium	Diminished	Diminished	Minimized

creased secretion of posterior pituitary antidiuretic hormone, resulting in the retention of water, which, with the retained salt, produces edema.

It is evident at a glance that if an "increase of capillary blood pressure" is substituted for "the development of a serum albumin deficit" the remainder of the sequence would follow unchanged (Table 4). If this sequence is in any large measure correct it has certain corollaries. First of all, the administration of water without salt should increase the

comparably elevated. It was obvious that she had developed acute diabetes insipidus. Since she could not take fluid this expressed itself in an extreme dehydration reaction. She was immediately given a continuous intravenous drip of glucose solution and intermittent injections of small amounts of pituitrin. The data are shown in Figure 2. Unfortunately the urine volume could not be recorded because urgency, together with her somnolent state, led to frequent

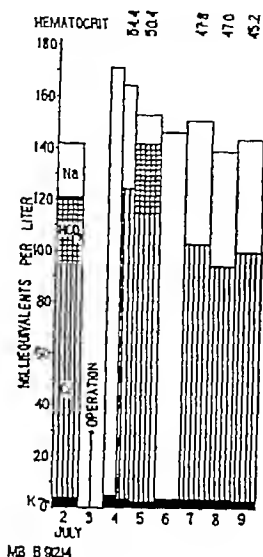

FIGURE 2. Concentration of Electrolytes in the Serum of a Patient Who Developed Acute Diabetes Insipidus after Operation for the Removal of a Cyst in the Third Ventricle

involuntary urination in the bed. The polyuria could not be entirely controlled by pituitrin because of the side reactions produced by this preparation.

This is a long, but necessary, preamble to the discussion of edema, which is limited chiefly to the subject of cardiac edema, because this includes most of the features involved in edemas of every kind and because the present controversy about the subject is challenging. The sequence of events in the production of cardiac edema has been conventionally conceived as outlined in the left-hand column of Table 3.

According to this concept failure of the heart causes the blood to back up, increasing the venous pressure and thereby the capillary blood pressure. This provokes transudation of fluid from the capillaries with consequent reduction of the volume of circulating plasma. This last, in turn, provokes the kidneys to reabsorb more than the usual quantities of sodium salts and water. This seems a logical sequence, compatible with existing physiologic theory.

Because, they claim, retention of sodium precedes the rise of pressure, and because measurements by

means of dyes indicate that the plasma volume does not contract, but rather expands, Warren and Stead<sup>17</sup> have proposed a reversed sequence, which they term "forward failure." According to this hypothesis the primary event is retention of sodium salts by the kidneys, which they attribute to some disturbance of the circulation to these organs. This leads to a similar retention of water. The consequent expansion of the volume of circulating plasma increases the capillary blood pressure, which, in turn, accelerates transudation and thus produces edema. From the standpoint of therapy the order of events is of great importance. The premises on which the theory of "forward failure" is based, therefore, require serious examination.

Those who would carry this theory so far as to suggest that the Starling principle is not operative in cardiac edema deserve no consideration, for

TABLE 3. Origin of Cardiac Edema

STARLING <sup>1</sup>	STEAD <sup>17</sup>
1 Increased venous pressure and capillary pressure	1 Retention of salt and water
2 Transudation	2 Expansion of plasma volume
3 Hemoconcentration	3 Increased venous and capillary pressure
4 Retention of salt and water	4 Transudation

reasons mentioned above. Since the venous pressure is increased in heart failure at one time or another, there must be back pressure in the capillaries that will inevitably provoke transudation. Landis<sup>18</sup> has pointed out that this is not delayed until gross salt retention has occurred. Patients with minimal heart failure excrete sodium salts normally and remain free from edema when they are at rest in the recumbent position, but develop edema when they are erect with legs dependent. This formation of edema, as Perera<sup>19</sup> has shown, is attended by hemoconcentration.

If Stead is right, reasons must be found for expansion of the blood volume and simultaneous retention of sodium. The latter, it has been shown, is the characteristic reaction to the need to conserve water. Why, then, should it be called into play when there is an obvious excess of water in the body? The disorders encountered in disease may be regarded as normal physiologic responses to unusual conditions produced by pathologic processes. It is proper, then, to assume that retention of sodium in heart failure is provoked by the usual stimulus, the need to conserve water. This term must, however, be interpreted in terms of the kidneys; it cannot be the actual need to conserve water to which the kidneys respond, but conditions that lead the kidneys to believe that there is a need to conserve water. (This decision may, of course, be made in the adrenal cortex or some other organ

to reabsorption of water is excessive concentration of sodium salts in the extracellular fluid. The question of the volume and location of the circulating blood and its regulation still requires open-minded inquiry.

I should not be altogether ingenuous if I did not admit that nervous control of renal function, of which physicians are only beginning to become aware and which has been neglected in this discussion, might prove to be an important factor in the phenomena of circulatory disorders.

Finally, sodium is spoken of more freely than available data warrant. The measurement of sodium has been a protracted, meticulous procedure for which few laboratories are equipped, and which is ill adapted to the regulation of therapy in the clinic. Sodium figures have been interesting chiefly in retrospect, too often as records of errors in the evaluation of other evidence. It has been generally assumed (and I plead guilty on this score) that the concentration of sodium can be estimated from the sum of the concentrations of bicarbonate and chloride with the aid of astute clinical observation. It is, of course, recognized that in diabetic acidosis and advanced renal insufficiency replacement of bicarbonate and chloride by other anions (ketone acids, phosphate, sulfate and so forth) invalidates such estimations.<sup>25</sup> The frequency with which such estimations fail in heart failure has been less widely appreciated. In fact, the concentration of sodium in the serum in heart failure has been more discussed than investigated.

The nature of all the discrepancies between sodium and bicarbonate and chloride in heart disease cannot be discussed for lack of time. Only one matter is truly relevant to the subject, the concentration of sodium salts in the serum in heart failure. If retention of these salts were the primary event in heart failure, serum sodium in this condition should be regularly elevated or in the upper normal range. Furthermore, the logical first measure in the treatment of cardiac edema would be the administration of mercurial diuretics, which specifically inhibit reabsorption of sodium salts by the kidney. This has indeed been advocated. It has even been claimed, without any adequate evidence, that these compounds have a beneficial action upon the heart itself. In a certain proportion of patients with heart failure, serum sodium is slightly elevated. But in another group, for reasons that have not been altogether elucidated, it may be subnormal.<sup>26</sup> In the latter, mercurial diuretics are distinctly contraindicated.

A man of sixty-three, with long-standing heart failure, having neglected to take his digitalis, was admitted to the hospital with a puffy face, orthopnea, distention of the neck veins, pulmonary congestion, bilateral hydrothorax, a greatly enlarged heart, an enlarged liver, probable ascites and massive generalized edema. The venous pres-

sure was equivalent to about 200 mm of water, the circulation time (dechlorin) was 40 seconds, and the vital capacity 1.5 liters. He was given 1 cc of mercurhydrin intravenously on admission, which provoked no diuresis. In fact, he voided only 150 cc of urine during the next thirty hours. On the morning after admission he seemed much worse. The blood nonprotein nitrogen was found to be slightly elevated, whereas the serum albumin, chloride and sodium were greatly reduced. Digitalization was begun at once, and on the following day, since chloride, sodium and bicarbonate were still low, he was given 500 cc of 3 per cent sodium chloride intravenously. His condition improved strikingly, and his urine volume increased. Within three days his weight had decreased 7 kg, and venous pressure had fallen to normal. In this case mercurials were obviously contraindicated. The low sodium presumably contributed, as it will, to the circulatory failure. There are exceptions even to the rule that salt must be withheld in heart failure. It is possible that digitalis alone would have been effective. The state of the patient was so critical that it was impossible to conduct the experiment one step at a time. Such cases constitute a challenge to those who argue for primary retention of sodium chloride in heart failure. Their incidence must not be overlooked by the clinician. Measurement of sodium should be more generally practiced as soon as simple and practical flame photometers become available.

\* \* \*

My object has been not so much to solve, as to pose, the problems of cardiac edema. I hope that I have clearly distinguished in the discussion fact from speculation. I have tried to emphasize that in the clinic, as in the laboratory, plausibility is no substitute for sound reasoning based on fundamental scientific principles, that generalization from particulars is dangerous, and that no single organ or system in a complex integrated organism can be considered *in vacuo* apart from the whole.

induced an excellent diuresis. By the end of six days she had lost 10.5 kg (23.1 lb). With this water a comparable quantity of chloride was excreted. At this point, when she was practically free from edema, further injections of albumin caused no further loss of weight or chloride. The immediate effect of the injections was to raise the serum albumin, which led to the absorption of fluid into the blood stream. Expansion of the circulating plasma was demonstrated by means of the hematocrit. The proteinuria, however, increased so greatly that the rise of serum albumin was not sustained after the injections were discontinued. After the injections were discontinued, although the serum albumin fell rapidly to its original level, the edema reaccumulated only gradually. At the same time urinary chloride sank to a minimum and remained there until the edema had reaccumulated. The retention of fluid kept pace with the retention of chloride, which may be considered as equivalent to sodium in this case. From the standpoint of salt and water, the primary factor in the development of the edema was salt. Its slow accumulation can be attributed to restriction of salt, water was at no time restricted. From this point of view the action of injections of albumin differs in no respect from that of mercurial diuretics, although its *modus operandi* is altogether dissimilar. Mercurial diuretics inhibit reabsorption of sodium, thereby removing the stimulus to antidiuretic activity. Albumin expands blood volume, thereby removing the stimulus to reabsorption of sodium salts.

Reduction of the volume of the circulating blood or plasma, therefore, appears to cause the kidneys to reabsorb salt in efforts to conserve water, even if there is an excessive amount of water in the body as a whole. Why, then, should the kidneys respond in a similar manner in heart failure if the blood volume in this condition is greater than normal? The presenting phenomena in fully developed heart failure are excessive transudation from the blood stream, as evidenced by the presence of edema, increased venous and capillary blood pressures, which should tend to diminish the volume of the circulating plasma, and increased reabsorption of sodium by the kidneys, a reaction usually provoked by contraction of the volume of circulating plasma. There is reason to believe that the degree of expansion of the blood volume in heart failure has been exaggerated. Heart failure presents precisely that combination of disorders in which dye methods should be most unreliable, a condition in which the liver is distended with blood and fluids containing large amounts of protein and dye. The evidence for expansion of volume by other methods is not altogether consistent. Stewart<sup>20</sup> found that diuresis in heart failure occurred only if the specific gravity of the plasma fell. In an article by Merrill and Stead<sup>21</sup> the most striking instance of diuresis

is associated with a sharp drop of hematocrit. In some of my own studies values for hemoglobin and hematocrit indicate hemoconcentration in heart failure. There is indubitable loss of fluid from the circulation in certain types of heart failure—namely, paroxysmal dyspnea and coronary occlusion. Stead and Ebert<sup>22</sup> are so impressed with the importance of expanded volume that they have advocated venesection for the treatment of the shock syndrome of coronary occlusion. That their patients died seems not to have dismayed them. Transfusions have been given to patients with the shock of coronary occlusion, with signal benefit. Unfortunately, preconceptions so prevail that this life-saving measure is too often delayed until the shock has become irreversible.

If retention of sodium and consequent expansion of blood volume were the primary causes of cardiac edema, further expansion of blood volume should have a deleterious effect. This has not been satisfactorily demonstrated. Hypertonic glucose has been advocated for the treatment of heart failure under the pretext that the glucose was required by the heart muscle. Actually, it produces transitory hemodilution. McCann and Brown<sup>23</sup> induced diuresis in a patient with congestive heart failure by intravenous injection of concentrated human blood plasma. I have recently given injections of salt-poor human serum albumin to patients with heart failure. The cases thus far selected have been of a desperate type, mainly patients with advanced renal insufficiency as well as heart failure. Although no striking successes can be reported, dire forebodings of disaster have not been realized.

Granted that the circulating blood volume is expanded, if the reasoning concerning renal activity is logical, it must be so expanded that the kidneys are unaware of it or do not participate in it. It is not inconceivable that the circulating blood is pooled somewhere—for instance, in the liver and other viscera—and is thereby diverted from the kidneys. If expansion of blood volume is a response to such a dislocation of the circulation it should be regarded as a compensatory or protective reaction, even if it should prove to be misdirected. It may, of course, be not the actual volume of circulating plasma but some function usually related to the volume of circulating plasma—such as renal blood flow—that apprises the kidney of the need to conserve water.

This is not idle speculation. If the earlier physiologic argument has adhered to fact, the rationale for restriction of salt in both cardiac and nephrotic edema is clear. The relative ineffectiveness of limiting the intake of water is also explained. To be sure, edema cannot be formed without water, but the strongest physiologic stimulus to reabsorption of sodium is dehydration produced by deprivation of water. And the strongest stimulus to thirst and

OBSERVATIONS

*Nail Changes in Vasospastic Conditions*

These consist of a remarkable thinning of the proximal nail fold, with a more gradual merging into the translucent cuticle. The latter membrane is greatly widened, and does not end abruptly at its distal or free edge, as it does normally. Instead it extends out for several millimeters, to merge almost imperceptibly with the nail plate (Fig 2)

FIGURE 2 Typical Lesion in Arteriospastic Disease  
*Widening of the cuticle ("pterygium") and thinning of the nail fold are observed in Raynaud's disease of long standing*

The cuticle lesion described is the one termed "pterygium" by dermatologists. Concerning it, Pardo-Castello<sup>3</sup> states

This epidermal membrane may in some pathologic conditions advance 2 to 3 or more millimeters over the nail plate and become adherent to its outer surface. This is seen accompanying such conditions as peripheral neuritis, leprosy, sclerodactylia, and atrophy of the nails of different nature. It is a common condition in the last two toe nails in apparently normal persons. It is also seen in onychophagia.

This picture may be found in apparently all varieties of vasospastic disease, including the cold, stiff, splinted extremity, more outspoken vasospastic states and, most characteristically, Raynaud's disease and scleroderma (Fig 2, 3, 4 and 5)

FIGURE 3 Pterygium in Disseminated Scleroderma

I am convinced that pterygium is characteristic of the severer grades of Raynaud's disease, especially in the fingers. It is an apparently constant finding in fingers in which secondary scleroderma has set in, and it seems to be an accurate herald of coming scleroderma if that change has not yet become evident. Moreover, pterygium is just as

characteristic in primary or generalized scleroderma as in the secondary form.

Pterygium may be seen in the toes, but less often and less pronounced than in the fingers (Fig 4). The fairly common normal pterygium of the toes,

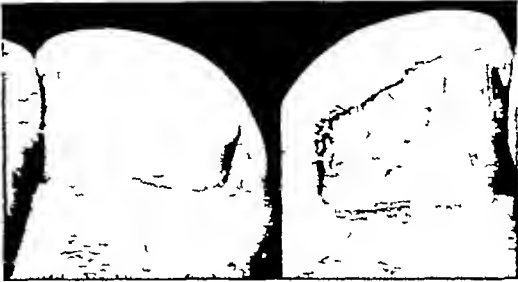

FIGURE 4 Pterygium in the Great Toes in a Patient with Post-Trench-Foot Syndrome

which is not characterized by thinning of the nail fold described above, is excluded from this discussion.

I have not seen the lesion developing in the presence of purely organic obstruction. On the other hand, it can be demonstrated in a variety of diseases, in all of which there are vasospastic reflexes mediated through the sympathetic nervous

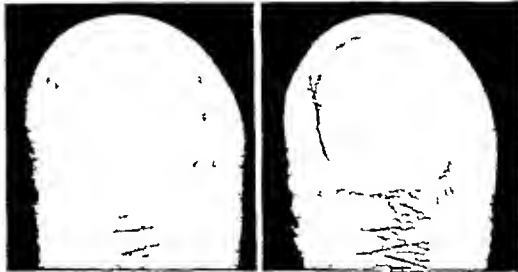

FIGURE 5 Correction of the Nail Lesion in Raynaud's Disease  
*In the photograph on the left, ten days after sympathectomy, typical changes are still present. In that on the right, five weeks after operation the nail fold has resumed its normal thickness and the cuticle its normal sharply delimited character.*

system. One may postulate either that the effect is due to the direct influence of nerve on tissue or that the mechanism involves a differential diminution in the various parts of the digital circulation. The latter possibility would be consistent with the known diminution in these diseases in the blood flow through the nail fold, from which the cuticle grows.

Whatever the mechanism, sympathectomy promptly does away with the lesion. In three or four weeks after the operation, the nail fold has become full, and the new cuticle is seen growing

## NAIL CHANGES IN FUNCTIONAL AND ORGANIC ARTERIAL DISEASE\*

EDWARD A EDWARDS, M D †

BOSTON

IT IS the purpose of this paper to show that the nails undergo specific changes in vasospastic and in organic peripheral arterial disease and are sensitive indicators of the severity of the underlying state

Raynaud<sup>1</sup> made more detailed notation of such changes than subsequent writers did Thus he

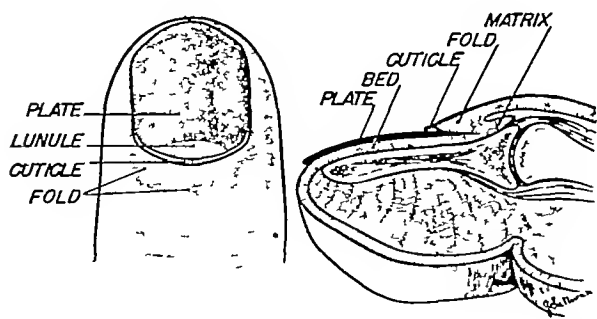

FIGURE 1 Normal Anatomy of the Nail

stated that the nails may be cast off by vascular disease attacking them at their "root", that growth of the nail stops during an episode of necrosis, and that they begin to grow when this episode is over, then showing a transverse depression, and that

ulceration of a digit may give loss of support of the nail at its extremity and result in a curving of the nail round the end of the digit Heller's<sup>2</sup> more recent monograph gives the impression that nail changes occur infrequently in vascular disease, consisting mainly of necrosis or ulceration concomitant with that of the digit He does mention that in scleroderma the nails are frequently involved by atrophy, thickening and deformation Pardo-Castello<sup>3</sup> states that in peripheral vascular disease, disturbances are frequent, with Beau's lines (transverse depressions indicating periods of retarded growth), partial loosening, atrophy, distortion and, finally, destruction by gangrene

Before these changes are considered it may be useful briefly to describe the normal appearance of the nail and its associated parts Reference may first be made to a longitudinal section of the nail (Fig 1) The nail plate, ordinarily referred to simply as the nail, consists of dead cornified material pushed distally by the growth of the parent cells of the nail matrix, and lying on the epithelial nail bed The surface of the digit shows the nail plate overlain by the skin, known here as the *nail fold*, which is arbitrarily divided into proximal and lateral parts The nail fold is cemented to the nail plate by its surface cornified cells, visible as the translucent cuticle The cuticle is thicker and more evident at the proximal nail fold, with a width of 1 mm or less It is all that remains of the eponychium that in the early embryo covers the entire nail plate One may also note the lunule, the white crescentic area of nail bed seen through the proximal end of the nail plate in the fingers

\*From the Department of Surgery, Tufts College Medical School. Aided by a grant from the Charlton Research Fund Tufts College Medical School

†Instructor in surgery Tufts College Medical School clinical associate in anatomy Harvard Medical School consultant in peripheral vascular diseases Joseph H Pratt Diagnostic Hospital surgeon-in-charge Vascular Clinic Boston Dispensary

An occasional change in pronounced ischemia due to a variety of diseases is so-called diffusion of the lunule (Fig 9). This appearance is described by Pardo-Castello as follows:

Diffusion of the lunula is a very common condition in leprosy and other dystrophic conditions of the extremities. The lunula loses its sharp anterior limit, spreads forward, and seems to invade all the nail bed. This is due to the formation in the nail bed of a granular layer loaded with keratohyalin, and finally results in defective cornification. Many cases of total leukonychia may be explained in this manner.

The distortion of nail growth gives rise to no apparent pain. The patient may complain of pain about the nails, however, if the ischemia is extreme. In such cases the local tissues are hyperesthetic, and the slightest pressure gives rise to severe pain. In the toes, the pain may be interpreted by both the patient and the doctor as due to ingrown toenail. Ingrown toenail may or may not be present, but it should be realized that the very recent onset of such symptoms in an older person is usually due to an ischemic hyperesthesia. Relief from the pain will be obtained by the cessation of weight bearing and an increase in arterial flow. Operative interference on real or imagined ingrown toenails in the presence of ischemia may result in gangrene.

#### *Nonspecific Lesions in Functional and Organic Disease*

In cases of great severity, the nail plates may be loosened and painlessly shed. This fact was mentioned by Raynaud<sup>1</sup> in several of his cases.

Primary infections of the nails are not seen with any characteristic frequency. On the other hand, the acral ulceration of arterial disease may involve the nails, with resultant distortions of their structure. Chronic subungual infection may also be seen in relation to the frequent ischemic osteomyelitis of the terminal phalanges (Fig 7).

#### SUMMARY

The nails show specific pathologic changes in both arteriospastic and organic arterial diseases and are sensitive indicators of the severity of the underlying state. In arteriospastic states, changes that may be grouped under the dermatologist's term of pterygium are described. They consist of a thinning of the nail fold and a widening of the cuticle. The normal abrupt demarcation between nail fold and cuticle, and between cuticle and nail plate is lost. Sympathectomy quickly restores the nail fold and cuticle to normal.

In organic arterial disease the nails do not show these changes. There is rather a thickening, roughening, and darkening of the nail plate, which hides the nail bed. An increase in arterial circulation by any means gives rise to a more nearly normal growth of the plate. Less specific changes include the growth of claw nails, or the presence of "diffusion of the lunule" in organic states, and the loosening and shedding of the nail plate in severe disease of either vasospastic or organic origin.

Painful nails are often an expression of the hyperesthesia of severe ischemia, in which operations for ingrown toenail usually cause gangrene.

Primary infections of the nails are uncommon in peripheral vascular disease, but the nails may be involved in acral ulceration, or may show subungual abscess over an osteomyelitis of the terminal phalanx.

in its normal, sharply delimited manner. Remnants of the old cuticle are seen adhering to the nail plate (Fig 5)

#### *Nail Changes in Organic Arterial Occlusion*

Severe ischemia, whether resulting from arteriosclerosis or from the less common thromboangitis

FIGURE 6 Typical Lesion in Organic Arterial Disease, Showing Distortion, Thickening and Pigmentation of the Nail Plate in Ischemia Due to Arteriosclerosis

obliterans, gives rise to a distortion of the growth of the nail plate (Fig 6). I have no data to offer on the likelihood that the same lesion occurs in other, less common, varieties of organic occlusion. There are no accompanying nail-fold and cuticle

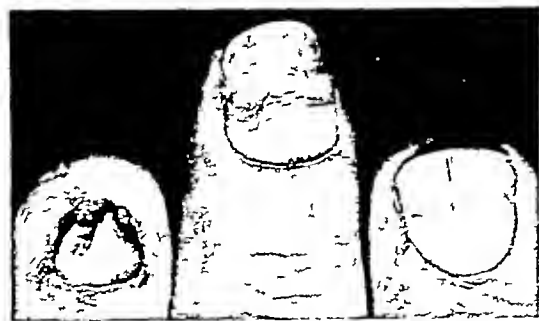

FIGURE 7 Improved Nail Growth in a Case of Buerger's Disease Four Months after Sympathectomy

The distorted plates are being displaced by a more normal growth. The distortion of the nail of the index finger (left) was associated with osteomyelitis of the terminal phalanx.

changes as seen in the vasospastic diseases. The linear growth is retarded to the extent that the nail may not have to be trimmed for months or years. The nail plate may gain in thickness, becoming heavy and rough. The roughening is usually caused by the presence of transverse or eccentrically placed, parallel ridging. The nail plate is darkened, but it is impossible to say whether this is due to a contained pigment or to external soiling of its roughened surface. The thickened and darkened plate effectively shuts off the underlying nail bed from view.

The distortion of nail growth may take the form of a claw nail (onychogryposis).

An increase of blood supply, obtained by any means, is signalled by a return of the roughened

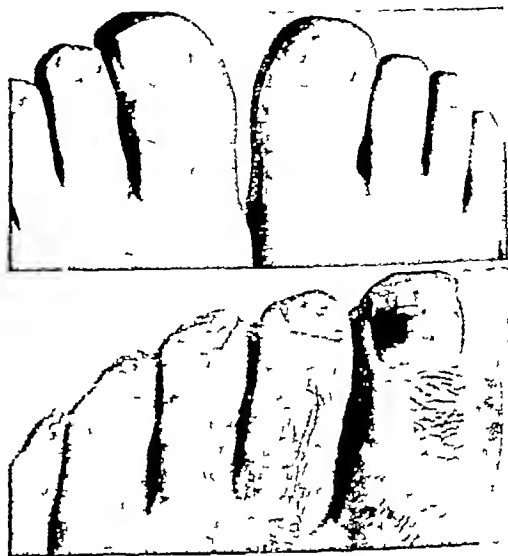

FIGURE 8 Improved Nail Growth in Buerger's Disease. In the upper photograph, taken after suction-pressure treatment, the deformed nail is being pushed forward by a more normal growth. In the lower photograph of the same patient, taken after a relapse two years later, a similar correction of growth followed the administration of testosterone propionate.

nail to normal growth (Fig 7 and 8). This results in a rapid distal displacement of the old mis-shapen nail by a new, more normal portion, through which may now be seen the nail bed, of a variable pink

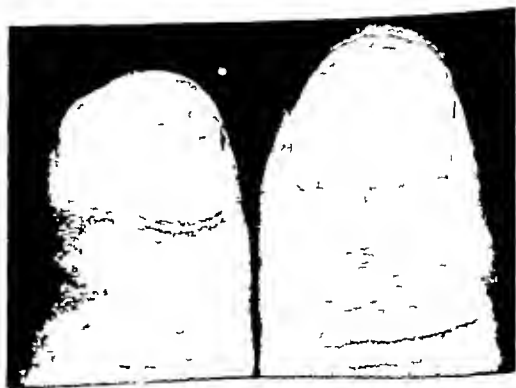

FIGURE 9 Diffusion of the Lunule in a Patient with Multiple Congenital Arteriovenous Communications of the Forearm, Hands and Fingers

The contrast between the old diseased nail and the newer, more normal portion serves as a striking indication of the improvement of the circulation. It is clinically useful to utilize the reversal of nail change in evaluating the benefit of therapy.

An occasional change in pronounced ischemia due to a variety of diseases is so-called diffusion of the lunule (Fig 9). This appearance is described by Pardo-Castello as follows:

Diffusion of the lunula is a very common condition in leprosy and other dystrophic conditions of the extremities. The lunula loses its sharp anterior limit, spreads forward, and seems to invade all the nail bed. This is due to the formation in the nail bed of a granular layer loaded with keratohyalin, and finally results in defective cornification. Many cases of total leukonychia may be explained in this manner.

The distortion of nail growth gives rise to no apparent pain. The patient may complain of pain about the nails, however, if the ischemia is extreme. In such cases the local tissues are hyperesthetic, and the slightest pressure gives rise to severe pain. ## A POSTOPERATIVE MASTECTOMY DRESSING\*

LEO H. POLLOCK, M.D.†

KANSAS CITY, MISSOURI

THE postoperative dressings of a radical mastectomy wound may be assisted and simplified by discriminate application of adhesive tape. This easy method, which I have used for many years, is not mentioned in the literature.

A strip of plain or elastic adhesive, 2.5 to 4.2 cm wide, is flamed. The strap is started over the lower

toral muscles. It then crosses the ridge of the shoulder to end over the upper part of the scapula. A thin piece of sterile gauze may be placed over the incision under the adhesive.

The procedure works very well with any type of skin incision, either transverse or longitudinal. The attachment of the skin flaps to the chest wall is helped by scattered mattress sutures, placed between them and by various types of pressure dressings. The important point in the method is the selective molding of the skin to the concavity in front of the head of the humerus before the outer

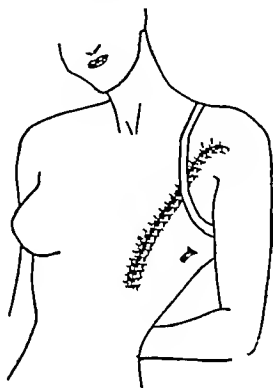

FIGURE 1 Curved Adhesive Strap, Molding the Skin to the Chest Wall in a Longitudinal Incision

This supports the posterior axillary fold to lessen the tension on the suture line. It greatly decreases the padding needed to obliterate the dead space.

aspect of the scapula. It is brought across the axilla by one hand as the other presses the posterior axillary fold anteriorly and upward. The medial

or upper skin flap is pushed toward the incision as the adhesive curves upward in the infraclavicular depression resulting from the removal of the pec-

FIGURE 3 Left Radical Mastectomy Wound on the Sixth Postoperative Day

The adhesive strip fits into the depression resulting from the removal of the pectoral muscles. This has obliterated the dead space. The full-thickness skin grafts are holding well. Tension on the edges is removed by the strip supporting the posterior axillary fold.

dressings are applied (Fig. 1). It minimizes the voluminous padding to obliterate the dead space. Also, the amount of padding is materially decreased by the application of similarly curved adhesive strips over it (Fig. 2). The strap supports the weight of the posterior axillary fold, which may be a dehiscent force in an obese or muscular patient. It lessens the circular constrictions on the chest that accompany swaths, binders and broad transverse adhesive straps relied upon for pressure.

The condition of the wound on the sixth day after operation is shown in Figure 3

Should a defect develop in the suture line, this method of strapping promotes healing by helping to approximate the edges and decreasing edema of both the skin and granulation tissue. One need

not remove the outer dressings to take out the drain. A heavy silk suture may be attached to the end of the drain and then fastened lineally to the lower edge of the outer pad. The drain may be extracted by pulling on the loose end of the thread.

## FAVISM\*

ALBERT P. ROSEN, M.D.,† AND JAMES J. SCANLAN, M.D.‡

PROVIDENCE, RHODE ISLAND

**F**AVISM as a cause of hemolytic anemia, though not uncommon in the Mediterranean basin, especially in Sardinia and Sicily, is rare in the United States. The first case to appear in the American literature was reported by McRae and Ullery<sup>1</sup> in 1933. Since then individual cases have been reported by Hutton,<sup>2</sup> Eads and Kash,<sup>3</sup> Josephs<sup>4</sup> and Wharton and Duesselmann.<sup>5</sup> It is the purpose of this report to review briefly the clinical features and possible etiology and to describe a typical case, as well as to call attention to the fact that the fava bean (broad bean) in addition to being imported is now being grown in this country. It appears very probable that many more cases would be discovered here if this entity were considered in the differential diagnosis of acute hemolytic anemia.

The syndrome, caused either by ingestion of the seed or by inhalation of the pollen of *Vicia faba*, is characterized by gastrointestinal complaints and sudden appearance of hemolytic anemia, followed by hemoglobinuria, jaundice and vascular collapse.

Symptoms occur after the inhalation of the pollen, in a matter of minutes to a few hours, after ingestion of the bean there is a delay of five to forty-eight hours. The symptoms vary in severity. A mild form is not uncommon, resulting in malaise, yawning, headache, vertigo, nausea, vomiting, diarrhea, pyrexia, abdominal pain and, at times, loss of consciousness. These symptoms usually disappear in a few days. The severer form includes hemoglobinuria, marked pallor and icterus. The urine becomes red or black. The icterus increases, and hepatomegaly and splenomegaly usually ensue. Recovery takes place within a week, but the symptoms may persist for several weeks. The blood picture during the attack reveals a marked reduction in red cells with anisocytosis, reticulated cells, polychromatophilic cells and erythroblasts. There is a marked leukocytosis during the first week. Death occurs almost only in children, and the mortality is 8 per cent.<sup>6</sup>

Three theories have been proposed in the pathogenesis of favism: infectious, toxic and allergic. Luisada,<sup>6</sup> in his comprehensive review of the Italian literature, presents a fair amount of evidence pointing to allergy as the mechanism in this syndrome. Robinson<sup>7</sup> also favors allergy, peripheral blood and bone-marrow smears in 3 of his cases revealed an increase in eosinophilic cells.

Sensitivity to the fava bean can be determined by skin tests, the optimum time being about six weeks after an attack. Apparently there is a refractory state during which skin tests are negative even in persons sensitive to the products of *V. faba*.

Josephs<sup>4</sup> points out that the disease appears to have a racial background identical with that of Cooley's anemia. Possibly this peculiar racial background serves to explain a manifestation of allergy that is certainly unique.

The treatment consists essentially of whole-blood transfusions to correct the anemia and of supportive measures. Epinephrine is recommended if there is vascular collapse.

## CASE REPORT

T. F. (C. V. C. H. 70704), a 5-year-old boy of Italian descent, entered the hospital on February 15, 1948, because of abdominal pain, red urine and jaundice of 30 hours' duration.

On the afternoon before entry, the child complained of crampy abdominal pains and vomited. That evening he complained of headache. The cramps continued intermittently throughout the night, and he had two loose, brown stools, neither of which appeared abnormal. His mother noted that his urine was "wine colored," a color that persisted with each micturition until admission. The temperature was 101°F, and he was observed to be "very pale." On the next morning it was noticed that his skin was yellow, and this became increasingly evident as the day wore on. The cramp-like abdominal pains recurred and he began to vomit frequently. A physician advised hospitalization.

The past history yielded no positive information concerning recent exposure to toxic fumes or chemicals. The patient had been apparently well until the sudden gastrointestinal upset. There were no cases of malaria in the family or immediate neighborhood. He had received no injections or transfusions and there was no history of familial anemia or of syphilis in either parent. However, two years before admission at the age of 3, he had had a similar episode of "jaundice" accompanied by nausea, vomiting, fever and the passage of red urine. This had lasted for 2 weeks and had cleared up spontaneously without medication. A further note

\*From the Pediatric Service, Charles V. Chapin Hospital.

‡Intern, St. Joseph's Hospital.

of interest in the history was the fact that the patient had had eczema in infancy and had a known allergy to eggs.

Physical examination revealed an acutely ill, pale and drowsy boy. He sighed and yawned conspicuously. There was a marked generalized lemon-colored icterus with an underlying pallor of the skin, the mucous membranes and scleras were markedly icteric. There was a moderate generalized lymphadenopathy. The eyes, ears, nose and throat were normal. The lungs were clear to percussion and auscultation. The heart sounds were loud and forceful, and there was a Grade III precordial systolic murmur. The apical rate was 130, there was a normal sinus rhythm, and the heart was not enlarged to percussion. There was generalized abdominal tenderness and some muscle guarding. The spleen edge, which was sharp and notched, was palpable 5 cm below the left costal margin. The liver was not palpated, but there was a suggestion of a mass in the right upper quadrant. The genitalia, extremities and nervous system were normal.

The temperature was 101.6°F by rectum, and the blood pressure was 98/68.

Examination of the blood revealed a red-cell count of 1,520,000, with a hemoglobin of 38 per cent (5.5 gm), and a white-cell count of 33,150, with 71 per cent neutrophils, 9 per cent large lymphocytes, 19 per cent small lymphocytes and 1 per cent eosinophils. The hematocrit was 35 per cent. The smear showed red cells with marked central pallor, anisocytosis, poikilocytosis, some target cells and spherocytes. There was moderate polychromatophilia and a reticulocyte count of 3.8 per cent.

The urine, which was Burgundy-red and had a specific gravity of 1.016, gave an acid reaction and contained 1.2 gm of albumin per 100 cc. of urine. It was packed with red cells, occurring singly, in clumps and in casts.

The patient was given 500 cc. of compatible whole blood in addition to 5 per cent glucose in water and saline solution. The next morning his color had improved noticeably, and the icterus had diminished in intensity. He was more alert and took soft-solid foods with relish. A second urinalysis yielded Burgundy-red urine, with a specific gravity of 1.025 and a neutral reaction, and containing 1.5 gm of albumin per 100 cc and rare red cells and a few white cells in the sediment.

The clotting time was 2 minutes, 33 seconds, and the bleeding time was 1 minute, 58 seconds. A cell-fragility test showed initial hemolysis in 0.38 per cent sodium chloride and complete hemolysis in 0.32 per cent.

The blood chemical findings were normal except for a slightly elevated icteric index.

X-ray films of the skull demonstrated some prominence of the digital impressions but no "hair-on-end" appearance or thickening of the skull table. The left hand had 4 carpal ossification centers, and the right hand 3 centers.

The temperature showed a mild elevation until the 4th hospital day, when it became normal. Recovery was uneventful. The icterus disappeared, the spleen receded, and the heart murmur became less prominent. The red-cell count on the 5th hospital day was 3,950,000, with a hemoglobin of 75 per cent. Daily urinalyses showed a rapid clearing and a gradual decrease in albumin content, as well as a disappearance of the cellular elements.

The etiology of the hemolytic episode was unexplained until at the suggestion of an attending physician\* an investigation into the history was made pertaining to the ingestion of fava beans. It was found that on the day before the onset of the illness, the patient's grandmother had cooked a quantity of fava beans, of which the patient had eaten four plates full. Further questioning revealed that the child had eaten fava beans just prior to the attack of icterus 2 years previously.

## DISCUSSION

The diagnosis of favism appears to have been warranted in this case on the basis of the history of two attacks of hemolytic anemia associated with the ingestion of fava beans and the physical and laboratory findings. Skin-testing agents for fava-bean sensitivity were not available at the time of

writing so that permission was requested of the mother, which she refused to grant, to feed the boy a few fava beans. In view of the 8 per cent mortality rate, the issue was not pressed.

Luisada<sup>6</sup> believes more cases will be seen in the United States for the following reasons: the fava bean is now cultivated in New York, New Jersey, Illinois and California, a large Mediterranean population lives in certain parts of the United States, and the fava bean is a staple article of the diet, and the beans are being imported from Italy as a canned food.

The beans can be purchased in practically all the grocery stores in the Federal Hill section of Providence, which is populated mainly by people of Italian background.

Apparently, the syndrome also affects peoples of Jewish stock. The bean is frequently used by them under the name of "bub." The case reported by Eads and Kash<sup>3</sup> occurred in a male of Spanish-Jewish descent. Robinson<sup>7</sup> reports 6 cases in Palestine in which the patients were at first thought to have Lederer's anemia. An interesting point in his paper may be worth repeating. There is evidence that the incidence of blackwater fever increases in March, the time of the ripening of the fava bean, and yet malaria in March is uncommon. This supports the observations of other authors<sup>4</sup> that a good many cases of favism have been misdiagnosed as blackwater fever because of the hemoglobinuria and splenomegaly. Wharton and Duesselmann<sup>5</sup> believe that some of the cases of hemolytic anemia classified as Lederer's anemia may possibly be explained by an allergic phenomenon similar to or identical with favism.

Apparently, the disease can affect any age group. Of the 5 cases reported in the American literature, 3 were in adults,<sup>1-3</sup> and 2 were in children.<sup>4, 6</sup> The case presented above is the sixth reported in the United States and the third case that involved a child.

All the American cases occurred in males, which follows the European trend in that males are affected much more frequently than females.

## SUMMARY

A case of favism in a five-year-old boy is presented with a review of the clinical features. More cases of this syndrome will be seen in the United States because the fava bean is now cultivated here.

## MEDICAL PROGRESS

### PREGNANCY TESTS (Concluded)\*

STANLEY L. ROBBINS, M D †

BOSTON

#### *Friedman Test*<sup>10</sup>

This technic was developed within a few years of the original mouse test and represents a modification employing rabbits in place of mice. It is based on the principle that female rabbits ovulate only upon stimulation by the male and, therefore, do not spontaneously ovulate or have corpora hemorrhagica. The administration of gonadotropin likewise produces ovulation and corpora hemorrhagica, and hence their presence after the administration of urine indicates a positive pregnancy reaction.

The technic for the performance of the test is composed of the intravenous administration of first morning urine into the ear vein with examination of the ovaries forty-eight hours later. The amount of urine administered and the number of doses employed vary widely from the original description of six doses of 4 cc each over a two-day period to a single injection of 15 to 20 cc of urine. Some laboratories are employing blood serum (6 cc) in place of urine with equally satisfactory results.<sup>86</sup> Inspection of the ovaries may be performed under anesthesia, and if the reaction is negative, the animal may be re-used, and the cost per test thus reduced.

The great advantage that this modification has over the Aschheim-Zondek test is its relative speed—forty-eight hours as compared to four to six days. Although follicle hemorrhage may occur as early as fourteen hours after the administration of the urine, it only becomes a definite reaction in twenty-four to forty-eight hours.<sup>87</sup> Larger doses of chorionic gonadotropin prove fruitless in speeding this change. Because of its relative speed the test has achieved widespread acceptance with invariably good results. The numerous reports in the literature cite accuracy from 100 per cent<sup>10</sup> to 98-99 per cent.<sup>61-64</sup> Certain drawbacks to the use of this technic are worth noting. It is necessary to have constantly at hand a colony of isolated, relatively large female animals, each weighing 3 or 4 pounds. The animals are very sensitive to toxic urines and are easily killed, and, thirdly, occasional focal hemorrhages that occur may closely

resemble true ovulatory hemorrhages, making the test difficult to read.

#### *Ovarian Hyperemic Tests*

One of the first effects of chorionic gonadotropin on the ovaries of immature rats is the development of a superficial hyperemia. This change appears within two hours and reaches its peak in sixteen to twenty-four hours, long before corpora hemorrhagica or corpora lutea appear. On the basis of this ovarian color change, numerous procedures have been developed, perhaps best referred to as the two-hour rat test,<sup>20, 21</sup> the six-hour rat test<sup>17</sup> and the twenty-four-hour rat test.<sup>12-16</sup>

As indicated above, the color changes produced in a positive pregnancy reaction begin in two hours. At that time the color change is subtle and is based on a comparison of the faint hyperemization of the ovary with the pale serosa of the other viscera. Since the urine in this two-hour technic is administered intraperitoneally, a resultant possible nonspecific inflammatory reaction of the other viscera may mask the slight ovarian color change. A great danger exists, therefore, of false-negative results, reported by Zondek, Sulman and Black<sup>88</sup> to be as high as 45 per cent. As more time elapses, the color change becomes more definite, but even the six-hour and twenty-four-hour tests have failed to gain wide acceptance because of this difficulty in reading the endpoint. It can best be summed up by saying that in the hands of the original investigators the procedures appear to give good results, but difficulty in reading the endpoint, for all but the most experienced, makes it of limited value to laboratories in general.

#### *Frog Tests*

As long ago as 1933 Shapiro and Zwarenstein<sup>11</sup> presented the first report of the use of the female South African frog in pregnancy diagnosis, based upon work by Hogben.<sup>89</sup> Subsequent references by these authors occurred in the ensuing two years,<sup>65, 66</sup> and in 1938 Elkan<sup>67</sup> introduced the procedure in England. Three years later Weisman and Coates<sup>68</sup> popularized this technic in the United States. Since that time numerous reports have appeared receiving the test with great enthusiasm. Accuracy is cited as between 96 and 100 per cent.<sup>90-93</sup>

The test is based on the fact that the female *Xenopus laevis*, like the rabbit, never ovulates un-

\*From the Mallory Institute of Pathology, Boston City Hospital.  
†Assistant professor of pathology, Boston University School of Medicine; instructor in pathology, Tufts College Medical School; instructor in pathology, Harvard Medical School; assistant pathologist, Mallory Institute of Pathology, Boston City Hospital.

less stimulated either by the male or by the administration of gonadotropic hormone. Hence, isolated female frogs, when injected with urine from pregnant women, react to a positive test by the extrusion of hundreds of grossly visible ova, usually in twenty-four and occasionally in forty-eight hours. If no eggs appear the test is negative. In either case, after an appropriate rest (four weeks after a positive test and one week after a negative test) the animal can be re-used throughout a ten-year to eleven-year life. Recently, blood serum has been found to be as useful as urine in this technic.<sup>84</sup> The advantages of this procedure are numerous. The endpoint is definite and simple to read—the presence or absence of ova. The speed exceeds that of the Friedman test. Re-use of the animals and their ease of maintenance make the procedure not only adaptable for small laboratories, but also very cheap. In 1946 Parker, Robbins and Lovelidge<sup>95</sup> succeeded in successfully rearing these animals in the United States and demonstrated the complete usefulness of these captive-bred amphibia for pregnancy diagnosis, thus removing the objection of the unavailability of these animals in this country. The sole remaining objection to the widespread use of this technic is the need to obtain and concentrate large volumes of urine, 40 to 80 cc, for each frog, a fastidious and protracted procedure. As pointed out above, in the course of breeding experiments it was noted that the male *Xenopus laevis* reacted to gonadotropic hormone and that this reaction was readily visualized by microscopical examination of the cloacal fluid. This reaction was further notable in that the male frog appeared to be considerably more sensitive to chorionic gonadotropin than the female, smaller quantities of urine sufficing to produce reactions in the male. Whereas concentrates of 40 cc of urine were required to produce a reaction in the female *Xenopus laevis*, 10 cc of whole urine sufficed for the South American male *Bufo arenarum* and 5 cc of whole urine for the North American male *Rana pipiens*. The technic of the test is essentially the same, using either the North or the South American frog. Only the quantities of substances administered differ. With the North American *Rana pipiens* 5 cc of whole urine or 5 cc of blood serum<sup>35, 56</sup> is administered to each of a pair of frogs. Cloacal fluid from the external cloacal orifice, obtained by use of a glass pipette, is examined unstained by the hanging-drop technic, one and two hours after injection. The reactions are clear cut, all or none, comprising the presence of spermatozoa in a positive test and their total absence in a negative test. As can be noted, the reaction develops within two hours, frequently in half an hour, and therefore the entire test sometimes requires only two and a half hours to perform. Re-use of the frogs is possible, but their low cost and the difficulty in feeding them make such use both unnecessary and

inadvisable. In the present state of knowledge, this reaction in the male *Rana pipiens* appears to be due to the presence of the luteinizing chorionic hormone. The frog does not appear to react to follicle-stimulating hormone derived from menopausal urine. An accuracy of 98 per cent has been achieved in this laboratory with this pregnancy test. Although this procedure still requires the use of animals, it most closely approaches in simplicity and speed the concept of a test-tube technic that is easy to read. Its value in the differential diagnosis of acute conditions of the abdomen with relation to ectopic pregnancy or any other emergency in which speed is of greatest urgency is obvious.

#### *Pregnanediol Test of Guterman*<sup>39</sup>

Of the several chemical procedures reported to be of use in the diagnosis of pregnancy, the only one that appears to hold any great promise is the test developed by Guterman.<sup>39</sup> This test is based on the observation by Venning and Browne<sup>10</sup> that pregnanediol is present throughout pregnancy although in low concentration in the first trimester. The test comprises essentially an extraction of the acid hydrolyzed pregnanediol and the development of a color complex by the addition of sulfuric acid. Reports of the accuracy of this procedure have been somewhat equivocal. Guterman<sup>39</sup> has recently cited his accuracy as 92 per cent in 248 tests, whereas Morrow and Benua<sup>42</sup> and McCormack<sup>44</sup> imply that low-titer urines may give false-negative reactions, and nonpregnant women with delayed menses may give false-positive reactions owing to the high level of corpus luteum hormone in the secretory phase of the menstrual cycle. The test has the fundamental disadvantage of dealing with the lowest titer of hormone when early diagnosis is required, in contrast to the extremely high titers of the last trimester when the diagnosis is obvious clinically. In conditions other than pregnancy associated with a high gonadotropic excretion, such as moles and chorionepitheliomas, this test is very useful since it is said to remain negative and therefore to differentiate these conditions from pregnancy.<sup>77</sup>

In the recent literature occasional reference is made to the various skin tests listed, to the histidine-excretion tests and to the prostigmine test. However, since these procedures in their present state of development contribute nothing to the diagnostic methods described above, they have not been described in any detail.

#### DISCUSSION

Any discussion of pregnancy tests must begin by emphasizing certain facts. All bio-assay techniques, which comprise the commonly used tests for pregnancy, depend in essence upon the presence in the urine or the blood stream of chorionic gonadotropic

hormone, the result of functioning chorionic epithelium in contact with the blood stream. It does not necessarily imply a living fetus. These tests, therefore, cannot distinguish between normal or abnormal pregnancies or tumors containing chorionic epithelium. It is possible in cases of intrauterine death of the fetus or of inevitable missed abortions to have viable, functioning chorionic tissue maintain a positive pregnancy reaction for some time. Moreover, even after all the functioning tissue has died, time is required for the excretion of the hormone already produced. Depending on the original level of hormone that existed, this time may vary from several days to a week. Rarely, cases of persistence of detectable chorionic hormone have been encountered months after total removal of a hydatid mole. When fetal death is suspected clinically and a positive pregnancy reaction is encountered, a repeat assay should be performed some time later, when the hormone is almost certain to have become lower or to have disappeared from the urine or serum. It is also obvious that in extremely early pregnancy negative reactions may be encountered, frequently termed as "false-negative reactions," when the test is performed before the prolactin titer has had time to rise to a detectable level. In general, the Aschheim-Zondek test, the Friedman and the frog tests are able to detect early pregnancy approximately seven days after the first missed period. However, since hormone titers of pregnancies show great variation from person to person, this time required for an adequate luteinizing hormone level to develop cannot be stated as an absolute time period applicable to all.

In many cases in which the test has failed to conform to the course that the pregnancy followed, the reaction has been termed an error in diagnosis. This use of the term "error" is unfortunate since at the time of the performance of the test the hormone titer may have been at some transitional level when the titer was either rising or falling. A test performed one or two weeks later would have dealt with a newly established level that would have conformed to the future course of the gestation.

The second point to be remembered is that no pregnancy test — and for that matter no laboratory test — is infallible. Reports constantly emphasize the closeness with which these various diagnostic procedures approach 100 per cent accuracy, rather than the percentage of errors inherent in each technic. Thus, although a test may be 99 per cent accurate, the one error in a hundred is small solace to the physician or patient who falls heir to this sole discrepancy. Technical errors and insensitive or physically unfit animals contribute to errors in diagnosis. Moreover, well documented cases of normal pregnancy are cited in which it was impossible to obtain a positive Aschheim-Zondek test.<sup>96</sup> Such cases are fortunately extremely rare,

nonetheless they contribute to the so-called errors in pregnancy diagnosis. It is perhaps only fair to point out that in the absence of these pregnancy reactions it has never been established that the so-called "negatively reacting" normal pregnancies ever elaborated any chorionic gonadotropin. So much for the errors inherent in the laboratory diagnosis of pregnancy.

The question whether urine or blood serum is a better substance to use in any of these diagnostic procedures is an important one. To the best of my knowledge at present they may be used interchangeably. Smith and Smith<sup>96</sup> have long advocated the use of serum because unextracted urine is frequently toxic, killing all the animals to which it is administered. This death of laboratory animals is a most bothersome problem in laboratory technique since time is lost, valuable animals destroyed and almost invariably before a successful test has been achieved the specimen that is being assayed is used up and time must be wasted getting a new specimen. Serum, by contrast, appears to be remarkably free of this objection. Although it might at first appear that the titer of hormone should be higher in the serum than it is in the urine, this conclusion is not correct. Zondek et al.<sup>98</sup> state on the contrary that the titer of hormone appears in lower concentration in the serum than in the urine. This fact is particularly true when first morning concentrated urine specimens are used, since the amount of hormone excreted in a twenty-four-hour interval is uninfluenced by the volume of urine and hence reaches higher levels in concentrated urines. It is for this reason that when urines are to be used for pregnancy diagnosis it is advisable to restrict fluids and use the first morning urine. Notwithstanding this differential in hormone levels, if blood serum is titered on frogs or rats against first morning urine in an unselected series of normal pregnancies, the serum appears to give results as good as if not better than those obtained with urine — that is, it appears to give higher titers. It is possible that this difference in hormone level is more apparent than real and may be due to either a renal threshold holding back serum hormone and producing a low urine titer or to the fact that the urine may, by its toxic effects, depress the sensitivity of the animals. In any event, in the interests of a less toxic, more constant source of hormone, blood serum appears to be preferable to urine.

Is it possible to say that any one of the tests described above is better than the others? No, since each procedure has its own peculiar advantages that suit it best to specific indications.

The Aschheim-Zondek test, despite the time it requires for performance, is to this day unsurpassed for accuracy, especially when the equivocal ovarian changes are controlled by microscopical slide examination. In view of the dual changes possible

less stimulated either by the male or by the administration of gonadotropic hormone. Hence, isolated female frogs, when injected with urine from pregnant women, react to a positive test by the extrusion of hundreds of grossly visible ova, usually in twenty-four and occasionally in forty-eight hours. If no eggs appear the test is negative. In either case, after an appropriate rest (four weeks after a positive test and one week after a negative test) the animal can be re-used throughout a ten-year to eleven-year life. Recently, blood serum has been found to be as useful as urine in this technic.<sup>94</sup> The advantages of this procedure are numerous. The endpoint is definite and simple to read—the presence or absence of ova. The speed exceeds that of the Friedman test. Re-use of the animals and their ease of maintenance make the procedure not only adaptable for small laboratories, but also very cheap. In 1946 Parker, Robbins and Lovelidge<sup>95</sup> succeeded in successfully rearing these animals in the United States and demonstrated the complete usefulness of these captive-bred amphibians for pregnancy diagnosis, thus removing the objection of the unavailability of these animals in this country. The sole remaining objection to the widespread use of this technic is the need to obtain and concentrate large volumes of urine, 40 to 80 cc, for each frog, a fastidious and protracted procedure. As pointed out above, in the course of breeding experiments it was noted that the male *Xenopus laevis* reacted to gonadotropic hormone and that this reaction was readily visualized by microscopical examination of the cloacal fluid. This reaction was further notable in that the male frog appeared to be considerably more sensitive to chorionic gonadotropin than the female, smaller quantities of urine sufficing to produce reactions in the male. Whereas concentrates of 40 cc of urine were required to produce a reaction in the female *Xenopus laevis*, 10 cc of whole urine sufficed for the South American male *Bufo arenarum* and 5 cc of whole urine for the North American male *Rana pipiens*. The technic of the test is essentially the same, using either the North or the South American frog. Only the quantities of substances administered differ. With the North American *Rana pipiens* 5 cc of whole urine or 5 cc of blood serum<sup>25, 86</sup> is administered to each of a pair of frogs. Cloacal fluid from the external cloacal orifice, obtained by use of a glass pipette, is examined unstained by the hanging-drop technic, one and two hours after injection. The reactions are clear cut, all or none, comprising the presence of spermatozoa in a positive test and their total absence in a negative test. As can be noted, the reaction develops within two hours, frequently in half an hour, and therefore the entire test sometimes requires only two and a half hours to perform. Re-use of the frogs is possible, but their low cost and the difficulty in feeding them make such use both unnecessary and

inadvisable. In the present state of knowledge, this reaction in the male *Rana pipiens* appears to be due to the presence of the luteinizing chorionic hormone. The frog does not appear to react to follicle-stimulating hormone derived from menopausal urine. An accuracy of 98 per cent has been achieved in this laboratory with this pregnancy test. Although this procedure still requires the use of animals, it most closely approaches in simplicity and speed the concept of a test-tube technic that is easy to read. Its value in the differential diagnosis of acute conditions of the abdomen with relation to ectopic pregnancy or any other emergency in which speed is of greatest urgency is obvious.

### *Pregnanediol Test of Guterman<sup>99</sup>*

Of the several chemical procedures reported to be of use in the diagnosis of pregnancy, the only one that appears to hold any great promise is the test developed by Guterman.<sup>99</sup> This test is based on the observation by Venning and Browne<sup>10</sup> that pregnanediol is present throughout pregnancy although in low concentration in the first trimester. The test comprises essentially an extraction of the acid hydrolyzed pregnanediol and the development of a color complex by the addition of sulfuric acid. Reports of the accuracy of this procedure have been somewhat equivocal. Guterman<sup>77</sup> has recently cited his accuracy as 92 per cent in 248 tests, whereas Morrow and Benua<sup>42</sup> and McCormack<sup>41</sup> imply that low-titer urines may give false-negative reactions, and nonpregnant women with delayed menses may give false-positive reactions owing to the high level of corpus luteum hormone in the secretory phase of the menstrual cycle. The test has the fundamental disadvantage of dealing with the lowest titer of hormone when early diagnosis is required, in contrast to the extremely high titers of the last trimester when the diagnosis is obvious clinically. In conditions other than pregnancy associated with a high gonadotropic excretion, such as moles and chorionepitheliomas, this test is very useful since it is said to remain negative and therefore to differentiate these conditions from pregnancy.<sup>77</sup>

In the recent literature occasional reference is made to the various skin tests listed, to the histidine-excretion tests and to the prostigmine test. However, since these procedures in their present state of development contribute nothing to the diagnostic methods described above, they have not been described in any detail.

### DISCUSSION

Any discussion of pregnancy tests must begin by emphasizing certain facts. All bio-assay techniques, which comprise the commonly used tests for pregnancy, depend in essence upon the presence in the urine or the blood stream of chorionic gonadotropic

this fall or rise in level obviously indicates recurrence of tumor. It is for these reasons that simple qualitative urine tests for the detection of the mere presence of a positive reaction have no value in postoperative tumor diagnostic work and are definitely to be discouraged since they may well cause totally unnecessary alarm.

### CASE 34361

#### PRESENTATION OF CASE

A six-year-old schoolboy entered the hospital because of persistent vomiting.

Until three weeks before admission the patient had no complaints. He then began to have anorexia and became moderately constipated. Eight days prior to admission he began to vomit on the average of one to three times a day. The vomiting was preceded by episodes of crampy, periumbilical pain. No fever had been present prior to admission.

Physical examination revealed a listless, rather poorly nourished boy lying flat in bed, with respirations of 40 to 50 per minute. A diffuse forceful apex impulse was visible extending almost to the anterior axillary line. A gallop rhythm was present, without murmurs or friction rubs. The remainder of the examination was negative. One observer felt the liver edge 3 cm. below the costal margin.

The temperature was 99.2°F., and the pulse 120. The blood pressure was 90 systolic, 66 diastolic.

Examination of the blood revealed 12.5 gm. of hemoglobin and a white-cell count of 13,000, with 51 per cent neutrophils, 34 per cent lymphocytes, 2 per cent monocytes and 13 per cent band forms. Urinalysis showed a specific gravity of 1.030, with no albumin, sugar or formed elements in the sediment. The serum nonprotein nitrogen was 23 mg., and the total protein 5 gm. per 100 cc. The pro-

thrombin time was 18 seconds (control 15 seconds). The sedimentation rate was  $\pm 5$  mm. per hour (normal, up to 20 mm. per hour). The Schick, blood Hinton and tuberculin (dilution of 1:1000) tests were negative for diphtheria bacilli.

A throat culture was negative for beta-hemolytic streptococci, diphtheria bacilli and pneumococci. An electrocardiogram showed a sinus tachycardia, with a rate of 160, and a PR interval of 0.13 second. The QRS complex was 0.07 second, and the T waves were flat in Lead I and inverted in Leads 2 and 3.

An x-ray film of the chest showed a marked increase in density in both lungs, more marked at the bases. The heart was enlarged, particularly to the left, with a cardiothoracic ratio of 11.5:18.5. A small amount of fluid was present in both costophrenic sinuses. The cardiac pulsations were diminished but regular. Diaphragmatic motion was free and equal. A plain film of the abdomen showed the liver to be slightly larger than normal. The spleen was not enlarged.

On the third hospital day the patient complained of pain below the tip of the sternum. The pulse rose to 160, and he appeared to be in shock. Following this episode he was placed in oxygen, and digitoxin was started, with definite improvement for the next few hours. During the next few days he remained about the same while digitoxin and oxygen were continued. A repeat electrocardiogram showed a rate of 140, with a PR interval of 0.14 second.

On the sixth hospital day the child was found to be drowsy, and later a right hemiplegia involving the face, arm and leg was noted. A lumbar puncture revealed a clear fluid and an initial spinal-fluid pressure equivalent to 170 mm. of water. No cells were present, and a Pandey test was negative. Repeat x-ray films at this time disclosed considerable mottled density in the right lung, radiating from the right hilar area peripherally. On the left, behind the heart, was a large area of dense lung. The

in the rat ovary, diagnosis of weak titers make the Aschheim-Zondek test of great value in detecting early gestations and complications of pregnancy such as miscarriages. The value of this weakly positive Aschheim-Zondek test has been brought out by Tenney and Parker.<sup>97</sup> In a series of 60 patients weakly positive tests, performed at a time when they should have been strongly positive, indicated in every case a complication of pregnancy. It is highly likely that assays performed on this same series with other technics would have yielded only completely valueless negative results.

The Friedman test has been up to the present time one of the most widely used tests because of its great accuracy and simplicity of performance. However, of recent date the shortage of rabbits and their rising cost have seriously discouraged many laboratories from the use of this animal. It was, in fact, these difficulties that catapulted the female *Xenopus laevis* into such wide usage. Not only was the female-frog test somewhat faster, but it was moreover, because of the possible re-use of the frogs, considerably cheaper. The male-frog technics at present appear to hold the greatest promise. The animals are widely available, easy to keep and cheap, and a positive diagnosis may be returned while the patient waits. Certainly, in cases of ectopic pregnancy, this procedure may prove life saving.

The determination of pregnanediol in the urine is the only chemical test for pregnancy of any significant value. It is unfortunate that its sensitivity is low in very early pregnancy and that its specificity has been questioned in cases of delayed menstruation. Further analyses are required to evaluate this technic more adequately.

No discussion of the laboratory diagnosis of pregnancy would be complete without a consideration of the functioning tumors, chorionepithelioma and hydatidiform mole. Inasmuch as these tumors usually develop after an abortion, miscarriage or pregnancy, their laboratory differential diagnosis from normal pregnancy is most important. It is well known that both of these tumors elaborate and excrete large amounts of gonadotropin, usually considerably more than that encountered in a normal pregnancy. Differences in the titer of hormone, as obtained in our laboratory, can best be expressed as pregnancy produces luteinizing hormone in the thousands of rat units, hydatidiform mole in the tens of thousands, and chorionepitheliomas in the hundreds of thousands. It is impossible to express these general differences any more specifically since enormous variation in titer may exist at different ages of the same tumor, and certainly between different tumors. The factors important in determining the levels of hormone that a given tumor will produce include the amount of chorionic tissue present, its proximity to blood supply and, most of all, the important question of whether it is a

functioning tumor capable of elaborating hormone. Not only are rare pregnancies incapable of elaborating chorionic gonadotropin but also rare hydatids and chorionepitheliomas may elaborate virtually no hormone. The exact explanation for this curious behavior is not certain, however, it is possible that the absence of this capacity is a function of the degree of anaplasia of the tumor. The well known tendency of these tumors to undergo necrosis is another cause of wide differences in hormone production. It must therefore follow that no arbitrary hormone titers for these tumors can be specified. In the differentiation of these tumors from pregnancy, on the basis of the level of hormone produced, careful consideration to the possible duration of the pregnancy must therefore be taken into account. At the peak production, titers of luteinizing hormone up to 15,000 rat units per twenty-four hours may be found in pregnancy. It is entirely possible for small hydatid moles or chorionepitheliomas to produce less hormone than this amount.<sup>98</sup> On the other hand, titers of hormone over 25,000 rat units for a twenty-four-hour sample and certainly over 50,000 rat units, according to the standards employed at our laboratory, almost certainly indicate the presence of either a mole or a chorionepithelioma.

In brief, quantitative assays of hormones may or may not be diagnostic of themselves, and, in general, they are best used as confirmatory evidence rather than diagnostic criteria. It should be emphasized that assays for hormonal titers or levels should be performed only on twenty-four-hour urine samples. Quantitative urine assays on spot samples of urine are of little value.

More difficult than the problem of differentiating pregnancy and neoplasms is that of following patients after surgical removal of one of these lesions. A widespread misconception prevails that after successful removal of a mole or a chorionepithelioma the hormone promptly disappears from the circulating blood and urine within a matter of a few days. It is not appreciated that the time required for the gonadotropin to disappear is extremely variable, depending not only upon the original height of the hormone level but also upon the rate of excretion of the hormone. As pointed out above, levels of detectable gonadotropin have persisted for months after successful removal of a mole.<sup>99</sup> Any single quantitative determination, then, is of limited value since it may represent persistence of hormone from the preoperative level. It is much better practice to follow the hormone level by serial quantitative titer assays so as to determine whether the hormone is increasing or decreasing in the blood. Falling levels, however long after the removal of a tumor they occur, can only signify that no new hormone production has occurred and that, therefore, the patient is free of functioning chorionic epithelium. Any reversal of

these areas one after another, and I think that a tumor would have been excluded by palpation of the abdomen, and certainly x-ray studies would have been instituted to determine whether one was present.

The second area of involvement appears to have been the heart. If we have some suggestion from the electrocardiogram of pericarditis, of pericardial effusion particularly, after the child had been in the hospital for three days, the episode of pain below the tip of the sternum might have been due to increase in pericardial fluid and pericarditis. The pain might also have been due to coronary obstruction with infarct of the heart or an extremely diffuse myocarditis. We have been seeing the latter frequently caused by an agent that is probably a virus rather than a bacterium. The heart shows definite involvement without evidence of interventricular or interauricular defect, congenital malformation or involvement of the valves.

The third area is the lung, and I am more perplexed now than on reading the description. I thought from the description that we were dealing with either an infarct or abscess or reaction to aspiration of vomitus. To explain the brain changes one could consider the possibility of metastatic abscess from the lung.

I mentioned previously the possibility of sarcoid involving the bowel as being responsible for the vomiting. There, too, we can find a possibility of involvement of the lungs and brain. We had such an experience recently in a child who had this disease and then hemiplegia many years after the initial bowel involvement.

This child had no evidence of a marked infection. The temperature was never high, near the end it was approximately normal, and there was very little change in the white-cell count. Yet the possibility of infection must be entertained seriously. The only infectious disease that might account for the changes would be subacute bacterial endocarditis, and we would have to assume involvement of the bowel with infarct. We are not given any evidence that that occurred — no blood in the stool and no other sign of infarct. But involvement of the bowel, the heart, the lung and the brain can be explained entirely by subacute bacterial endocarditis.

I have not mentioned the other possibilities of vascular disease. If we assume vascular accident or infarct in the brain, we should mention periarthritis nodosa, which is capable of producing all these changes in various locations. We should mention rheumatic fever with arteritis and diffuse myocarditis, possibly occurring in an extremely early attack with no evidence of previous damage to the valves. If the child lost a great deal of fluid during these three weeks of vomiting, presumably dehydration might have been of great importance, and then the possibility of sinus thrombosis must be entertained, with secondary cerebral hemorrhage and necrosis.

I am afraid I have exhausted the list of probable causes of such a group of changes, and I find nothing in the record that would permit me to make a positive diagnosis with any degree of confidence. I think that if I were to choose the most likely diagnosis to explain everything, I would choose rheumatic fever, rheumatic myocarditis, with arterial involvement in a number of places. I am not sure that would go with the pulmonary picture that we have demonstrated by x-ray examination. I think I would have to explain the brain hemorrhage, which this must have been, on the basis of arterial lesions in the brain on a rheumatic etiology or possibly secondary to the complication of the vomiting and rheumatic fever — also, aspiration abscess in the lung with metastasis to the brain. I can go no farther than that.

A PHYSICIAN: What about the congenital heart disease?

DR. FARBER: That is what I had in mind when I mentioned subacute bacterial endocarditis superimposed on an interventricular or interauricular defect, which would be responsible for very few symptoms and would explain why nothing was picked up earlier.

DR. TRACY B. MALLORY: What was the diagnosis on the ward, Dr. Wallace?

DR. WALLACE: We thought that the patient had myocarditis, but we could not determine the etiology. We thought he probably had a thrombosis or infarction to account for the cerebral signs.

A PHYSICIAN: Were any blood cultures taken?

DR. WALLACE: Two — and they were both negative.

#### CLINICAL DIAGNOSIS

Acute myocarditis, type undetermined

#### DR. FARBER'S DIAGNOSES

Rheumatic fever, with rheumatic myocarditis and arteritis?

Subacute bacterial endocarditis, with multiple infarcts?

Aspiration of vomitus, with lung abscess and metastatic brain abscess

#### ANATOMICAL DIAGNOSES

*Cardiac hypertrophy, idiopathic*

*Cardiac mural thrombosis, both ventricles*

*Embolism and infarction of lung, kidney, spleen (and brain)*

*Myocardosis, focal*

*Endocardial thickening*

*Focal necroses of liver*

*Hydropericardium, slight*

*Pericarditis, fibrous, localized*

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: Dr. Castleman scheduled this case for discussion, asked Dr. Farber to present the clinical side and me the pathological side, and then wisely left town. I wish that Dr. Farber were

bronchial markings throughout this region were observed to terminate very close to the origin of the left main bronchus, which was elevated above its usual position. The area of density lay within the posterior portion of the lower lobe. There was a small area of emphysema adjacent to the lower lateral heart margin. In the upper portion of the left lung mottling of the lung parenchyma was noted, similar in character to that noted on the right. There was a small amount of fluid within the pleural space on the right, particularly notable within the minor septum.

Penicillin and aspirin were administered without appreciable effect. The temperature, which had become elevated prior to the onset of hemiplegia, remained slightly elevated during the remainder of the hospital course, fluctuating between 99.6 and 100.4°F. The white-cell count showed a rise to 17,500, with 90 per cent neutrophils. The patient continued to fail slowly, and the nonprotein nitrogen rose to 72 mg per 100 cc. He was seen by numerous consultants during the next few days. On the sixteenth hospital day he died, approximately eight hours after a second cerebral accident.

#### DIFFERENTIAL DIAGNOSIS

DR SIDNEY FARBER\* May I ask for a cardiac expert to interpret the electrocardiograms?

A PHYSICIAN They could represent pericarditis.

DR FARBER I would like to ask for one or two bits of information before going on. The first question has to do with the character of the vomitus, whether it appeared in relation to meals and whether there was any blood in it. Also was there any blood in the stools at any time?

DR EDWARD P. WALLACE The vomitus was bile stained and related to eating. The boy took fluids but did not vomit while in the hospital. One stool specimen was normal.

DR FARBER He did not lose enough chloride to cause you to replace them artificially?

DR WALLACE One chloride determination was normal.

DR FARBER I wonder if we might see the x-ray films.

DR STANLEY M. WYMAN The films of the chest show a definitely enlarged heart without characteristic configuration. One cannot trace the posterior border adequately, but it appears to protrude backward considerably farther than usual. Throughout both lung fields there is a poorly defined, hazy mottling extending peripherally almost to the extreme lung margins. At this time the pleural spaces appear free of fluid. The liver margin comes down to the crest of the ilium, the liver may be slightly enlarged. The next examination five days later shows the heart shadow still larger but the film was taken with the patient lying on his back, and the x-ray tube was closer to the patient, causing

some magnification. The right-lung field has not changed materially, nor has the left upper lung. In the left-lower-lung field, however, behind the heart is a sharply defined area of density without any visible pulmonary markings in this region. The bronchi coming to this area extend a distance of 3 cm and terminate in an irregular fashion. The left main bronchus appears definitely elevated and compressed. The question arises whether the density lying behind the heart is in the lung or adjacent to the lung in the mediastinum. Again, I cannot identify the upper posterior heart border in the lateral view. There is very little, if any, fluid in the pleural spaces.

DR FARBER Is the consolidation of the lung consistent with an infarct?

DR WYMAN I cannot point to a definitely localized lesion to suggest infarct. The picture seems to be too diffuse and widespread and to emanate from the hilus.

DR FARBER Is there evidence of aspiration of vomitus, with occlusion of the bronchus in the next to the last film?

DR WYMAN It is conceivable, but I do not see any lung markings at all in that area. It would make me assume that the lung was "drowned", yet I can trace the bronchus down a fair distance. I believe that fluoroscopically the heart showed diminished but regular pulsations.

DR FARBER I confess that I am a little more confused than when I read the history. Some of these x-ray findings are not what I would have anticipated from the history.

I can begin in several different ways. The first and most obvious is to begin with the vomiting. The patient was well until the onset of the illness, which began five weeks or so before he died. We must assume that he was well until that time. We assume also that he had no abdominal operation previously and that adhesions, volvulus and obstruction cannot have played any part in this history. Among the conditions that could be responsible for this picture we must mention congenital malformations and tumors of the bowel involving the duodenum or a duplication of the duodenum, jejunum or stomach. Vomitus preceded by periumbilical pain could be produced by pressure from without, by tumor or by infection of the bowel or an inflammatory process such as that found in sarcoidosis. I think we ought to consider whether we should think of neoplasm any further. The story is perfectly consistent with the occurrence of a tumor either within the wall of the bowel or in the region of the intestinal tract with compression of the bowel. If we were to think of the most common tumors to do this, we would mention lymphosarcoma, with or without leukemia, the embryoma of the kidney or unattached in the kidney region and neuroblastoma. It is conceivable for lymphoma particularly to involve all

\*Pathologist in-chief, Children's Hospital, Boston.

beneath this there were several small cystic areas. In one portion there appeared to be expansion and erosion of the cortex of the bone. An intravenous pyelogram was negative.

The patient was suspended in Russel's traction, and later a Kirschner wire was inserted in the proximal right tibia for traction. Further x-ray examination revealed numerous areas of diminished density within the calvarium, limited mainly to the diploe. The thoracic spine showed only scoliosis and moderate hypertrophic changes. Changes interpreted as metastatic involvement were seen in many ribs, and there was a fracture in the seventh rib. A suggestion of several lytic lesions was noted in the scapula and in the body of the left humerus. No lesions were seen in the lungs though they could not be ruled out. Several suggestive areas were seen in the left pubis and ischium, and a definite, rounded, lytic zone was present in the right wing of the ilium. A small cystic zone was visualized in the left carpal navicular. A repeat examination of the calcium and phosphorus showed no essential change from the initial examination. The alkaline phosphatase at this time was 1.7 units per 100 cc, and on one occasion the calcium was 12.6 mg per 100 cc. The twenty-four-hour urinary-calcium excretion was 101 mg. On the eighth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR OLIVER COPE. The patient had a pathologic fracture in the midshaft of the right femur. The description of the physical examination gives no clue regarding the origin of the disease. Since the positive laboratory observations — cells in the urine, a slightly elevated white-cell count, a mild anemia, subnormal blood serum protein and an elevated blood serum calcium determination in one of presumably several determinations — are either inconsistent or bear no relation to bone disease, they must be dismissed as uninformative. The entire written record, therefore, is of no help in clarifying the diagnosis, and we must turn to the roentgenographic examination. Realizing the importance of the roentgenogram, Dr Castleman allowed me the privilege of reviewing the available films before starting this discussion.

Before examining the films, let me tell you how I approach such a problem — how I classify bone disease according to its distribution. The distribution of disease in bone may be divided into four categories: generalized, segmental, localized and warm bone involvement. Generalized bone disease occurs when the stimulus to bone disease is truly general, as in endocrine diseases and nutritional deficiencies. In endocrine diseases the hormonal disturbances are registered throughout the skeleton. The common hormonal diseases in this category are hyperparathyroidism, hyperthyroidism, adrenal cortical hyperfunction, anterior pituitary disturbances and perhaps acute gonadal disturbances. The

nutritional deficiencies have a generalized distribution because all regions of the skeleton are exposed equally to the deficiency. For example, vitamin D deficiency, giving rise to rickets in children and osteomalacia in adults, shows changes generalized in distribution. So also with vitamin C deficiency and protein deficiencies interfering with bone matrix.

In the segmental type of distribution the bone disease follows the distribution of a peripheral nerve or nerve root. The Albright syndrome, or fibrous dysplasia of bone, is the classic example in which the bone lesions are thus distributed. This disease has been termed disseminated, but though the lesions are often disseminated, the word is not critically descriptive.

Localized disease of bone may originate anywhere in the skeleton as a result of either primary osseous or primary marrow tumors. The primary osseous tumors are commoner in the younger age group and occur most frequently near the rapidly growing bone — that is, in close relation to an epiphysis. The primary marrow tumors are those arising in one of the various tissues encountered in bone marrow, such as the endothelioma of Ewing, the myelomas and hemangiomas. Since these tumors bear no true relation to bone tissue they are found anywhere in the bone, bearing no relation to epiphyses.

Warm bone disease is the type of distribution encountered when malignant tumors and lipid dystrophies, having a primary origin outside of bone, spread to the skeleton. The use of the word "warm" has a theoretic reason: that malignant tissue spreading to bone grows best in the warm areas. Metastatic lesions from cancers of the thyroid gland, breast, kidney and prostate are found less commonly in the bones of the distal extremities, which are less well covered with muscle and fat and are colder than the centrally located bones. In the metabolic disturbances, such as the Schüller-Christian syndrome, a similar warm bone distribution is found.

This is a peculiar case because although at first sign the distribution appears to be generalized (films of the entire skeleton are not available), the primary lesion, that of predominant interest, the right femur, can fit only in the category of localized bone disease. Let us look at the films. Dr Wyman, tell us where you see disease.

DR STANLEY M. WYMAN. As Dr Cope has said, all the films are not available. The presenting bone, the right femur, shows this rarefied bone-expanding lesion without significant reaction about its margins. There is a pathologic fracture through the center of this area of rarefaction. Lower in the same bone there are multiple, rather sharply defined areas of rarefaction. They are lesions that expand the cortex somewhat.

DR COPE. They are clearly punched out. I think you will agree that some of the areas in the acetabulum and skull are sharp and well defined.

discussing the pathological side because I have not the slightest idea what this boy suffered from. I can tell the anatomical findings quickly and briefly. There was an excess of fluid in the pericardium—70 cc—and a few fibrous adhesions. Microscopically a few lymphocytes were found in the epicardium. The heart was very much hypertrophied, being two and a half times the normal size. The valves showed a barely perceptible elevation here and there but no frank vegetations. The coronary arteries were normal. Microscopically the myocardium showed many small foci of absorption of muscle fibers of varying ages. One person who looked at the heart, knowing nothing of the age of the patient or the gross findings, said that it looked like coronary-artery disease. That was my first impression when I looked at it. The endocardium of the left ventricle was distinctly thickened, and overlying the endocardium at the apex of both left and right ventricles were numerous adherent, partially organized thrombi. So we had a source for embolism in both major and minor circulations. There was infarction of the lung. There was also a rather extensive focal atelectasis with overdistention of the respiratory bronchioles and complete collapse of alveoli in many areas. There were infarcts of the spleen and kidneys, but we could find nothing to explain the episodes of abdominal symptoms. We did not have permission to examine the brain, but without much question emboli were there also.

I have no idea how this case could be put together in any specific disease. We have what seems to be a primary extensive thrombosis within both ventricles, overlying thickened but not actually damaged endocardium. Nowhere in the valves, endocardium or myocardium do we have anything remotely suggestive of Aschoff bodies to permit a diagnosis of rheumatic infection, and nowhere in the sections did we find a vascular lesion. We have a slide here. Perhaps Dr. Farber can look at it and name the disease for us. The muscle cells are frankly hypertrophied for a child of this age. Here is one of the little patches of absorption where the muscle fibers have disappeared, with little reticulum and capillaries left. Most of these are old enough so that the muscle fibers have disappeared. There are one or two acute foci elsewhere between the columnae carneae where the endocardium goes into the myocardium. We found thrombi in varying stages of organization. In some places the muscle cells are markedly vacuolated, some degree of vacuolization is not uncommon, but this would be considerably more than normal.

In the liver there was extensive necrosis with congestion, and I am unable to say that it was on a degenerative or toxic basis. In many lobules two thirds of the liver cells were dead.

Can you offer any suggestions, Dr. Farber?

DR. FARBER: No, usually when I have entertained people here as a pseudoclinician, I comfort

myself by going back to the microscope. Here I have no such comfort. We have had examples of diffuse endocardial damage with emboli breaking off, without any suggestion from post-mortem examination concerning the exact nature of the underlying disease.

A PHYSICIAN: Nothing is said about a murmur.  
DR. WALLACE: No murmur was ever heard.

### CASE 34362

#### PRESENTATION OF CASE

A seventy-two-year-old widow was admitted to the hospital because of a fracture of the right femur.

Two weeks before admission the patient first noted pain in the right thigh when walking. Massages and local applications gave no relief, but she continued with her usual work of housekeeping. Two days previous to admission the right leg suddenly collapsed while she was walking. There was severe pain in the right thigh, and she was unable to walk. She was admitted to another hospital, where x-ray examination revealed a fracture of the right femoral shaft; she was then admitted to this hospital.

The patient had developed deafness at the approximate age of forty-five. A sister and a son had early deafness.

Physical examination revealed moderately severe deafness. The heart was slightly enlarged to the left. A loud, harsh, apical systolic murmur was widely transmitted. A thorough pelvic examination, though unsatisfactory, was essentially normal. There was tremendous swelling in the right midfemoral region, with crepitus, shortening and external rotation of the right leg. The hands showed mild rheumatoid changes at the metacarpophalangeal joints.

The temperature, pulse and respirations were normal. The blood pressure was 140 systolic, 80 diastolic.

The urine had a specific gravity of 1.022 and gave a + test for albumin, and the sediment contained 2 red cells, 20 pus cells, 10 epithelial cells and + bacteria per high-power field. It contained no Bence-Jones protein. The blood hemoglobin was 11 gm, and the white-cell count 13,300, with 80 per cent neutrophils, 11 per cent lymphocytes and 9 per cent monocytes. The nonprotein nitrogen was 29 mg, the calcium 9.9 mg, and the phosphorus 4 mg per 100 cc, the alkaline phosphatase was 4.4 units. The total protein was 5.3 gm per 100 cc, with 3.61 gm of albumin and 1.69 gm of globulin. A cytologic study of a vaginal smear was negative.

An x-ray film of the right femur showed a transverse fracture through the middle third of the shaft, with the distal fragment displaced posteriorly for a distance equal to the diameter of the bone and over-riding 6 cm. The fracture was through a large cystic area in the middle third of the shaft, and

## ENGLAND ABANDONS COMPULSORY VACCINATION

THE Englishman, whose home is his castle, and who has for centuries stubbornly defended certain hard-won principles of personal freedom does not give up his rights without a struggle. A respecter of the law, he still may evade a law that does not please him and only extreme circumstances will force him to turn as he has done, to an authoritarian form of government.

The National Health Service Act provides a surprising example of the way in which such a government can take away with one hand and give with the other. Restricting many of the rights of the free-born Englishman in the practice of medicine it gives to the entire population (perhaps a sordid boon) freedom from compulsory vaccination against smallpox.

This surrender of compulsion in vaccination is not a complete right-about turn as the history of vaccination in England shows. Greenwood\* briefly tells the story.

For ninety-five years, with various modifications, vaccination of infants has been compulsory in England. In the early years of this period the provisions of the law changed little, and something over 60 per cent of infants were actually vaccinated, with the percentage increasing until, about sixty years ago, the law was observed in the cases of nearly 90 per cent of the infants born. Opposition to the Act then became firmer, and the vaccination rate dropped back nearly to the original 60 per cent. At about the turn of the century public vaccinators were required to visit the homes of infants, and the rate rose again to 70 per cent, dropping with further modification of the Act, to approximately 35 per cent, where it has remained ever since.

Now, in the land of Jenner's birth and within a few months of the two hundredth anniversary of that event and of the announcement of vaccination approximately the one hundred and fiftieth, compulsory vaccination has been entirely abandoned.

The decline in vaccination that has led up to this startling decision is not Dr Greenwood believes, a consequence of antivaccination propaganda, but has resulted from two facts. The first is that few Englishmen under sixty have had any experience with severe smallpox, and the second that vaccination has been known to have severe consequences. Postvaccinal encephalitis it is true, is extraordinarily rare, but it has occurred.

Compulsory vaccination, in Dr Greenwood's opinion, would be returned if it could be demonstrated that an epidemic of severe smallpox would inevitably result from its neglect. Such a promise, fortunately, cannot be made. British experience has shown on the contrary, that the introduction of classic smallpox into a poorly protected community does not automatically give rise to a major epidemic so long as means are at hand for the immediate vaccination of those willing to be vaccinated.

Endemic smallpox is thus invited, on the assumption that prompt vaccination will prevent sporadic

\*Greenwood M. End of compulsory vaccination. *Brit M J* 2 22-24 1948

DR WYMAN Yes, there are some in the ribs, pelvis and skull. The bones of the hands show no definite lesion. The left femur appears essentially normal, what I can see of it.

DR COPE It is the right femur and the left acetabulum that are affected.

DR WYMAN The left femoral shaft is normal. The interesting thing about the films is that the uninvolved bone appears fairly dense and of good normal texture, especially for a woman of seventy-two years. It is unfortunate that she has no teeth so that we cannot examine the lamina dura.

DR COPE Let us concentrate on the right femur and for the moment forget the other bones. There are multiple lesions, and all are in the lower half. There is nothing that I can see in the upper half. Is that right?

DR WYMAN Yes.

DR COPE This distribution immediately eliminates a metastatic tumor. If these lesions came from the thyroid gland, kidney or breast, the lesion should be concentrated in the upper half of the bone. On this distribution, therefore, I exclude renal and the other metastatic tumors. I cannot see that it follows the skeletal distribution of the Albright syndrome. The right femur is the major area of illness, and yet there is nothing in the right side of the pelvis. There are lesions in the left acetabulum but none in the left leg. Films of the arms to go with those of the hands are missing. As there is a questionable lesion in a carpal bone on the radial side, if there were lesions in the radius and in the ulna, it would be conclusive of the Albright syndrome.

It is hard to explain the appearance in the skull if you do not agree to a tumor that is metastasizing.

There is inconsistency in the pattern with which we are dealing. I cannot go any farther on the evidence available than to say that this was a disease primary in bone.

What kind of primary tumor was it? Was it an osteogenic sarcoma? It obviously was not, for there was no bone formation. The patient's age is also against such a tumor. Because of the clearly punched-out areas, I am going to take another long shot and say that it was not a primary osseous tumor, but a tumor arising in the bone marrow. Was it a hemangioma? Was it an endothelioma of Ewing? This tumor is also not usual in patients of this age. What other kind of tumor could it have been? There are a variety, of course that can arise.

DR BENJAMIN CASTLEMAN What did you have in mind so far as bone-marrow tumors are concerned? Do you mean tumors like lymphoma or myeloma?

DR COPE It could have been a myeloma. Multiple myeloma is ordinarily accompanied by a high total protein. This patient's total protein was 5.3 gm per 100 cc, which is low, and one cannot get a lead from the record.

DR BERNARD JACOBSON Why do you exclude metastatic carcinoma?

DR COPE The distribution in the bones is wrong, and there is no primary lesion.

DR JACOBSON Did she have a pyelogram?

DR COPE Yes, but a negative pyelogram does not exclude a hypernephroma. There ought to be more metastases around the pelvis and fewer metastases at the lower end of the femurs if it were hypernephroma or carcinoma of the thyroid gland or breast. Dr Castleman extracted myeloma out of me, and the skull picture is characteristic of myeloma. A few years ago we had a patient about whom everybody disagreed. The x-ray films of the skull were put on the screen and everybody took a shot at them. Dr Albright and I said multiple myeloma, Dr Sosman said hyperparathyroidism, and Dr Holmes suspected some kind of hemangiomatous tumor because of the connection of the punched-out areas in the skull with the venous sinuses. It turned out to be metastatic hypernephroma, so that one can be wrong on the basis of the x-ray films. In the final analysis dependence has to be placed on a biopsy of a lesion. I have tried to present to you how I personally attack such a problem. Yet I know on the evidence one cannot be flat-footed about making a diagnosis.

#### CLINICAL DIAGNOSIS

Metastatic carcinoma

#### DR COPE'S DIAGNOSIS

Primary bone-marrow tumor

#### ANATOMICAL DIAGNOSIS

*Multiple myeloma*

#### PATHOLOGICAL DISCUSSION

DR CASTLEMAN On the wards this was believed to be a metastatic tumor, myeloma was ruled out, as Dr Cope suggested, by the low serum protein and the absence of Bence-Jones protein. A biopsy, however, did show a definite plasma-cell myeloma.

DR COPE That fits with the configuration in the skeleton. We have had myeloma with a normal protein and a normal Bence-Jones, and Dr Aub pointed out to me that when a case is in remission and is not in an active phase of proliferation, the Bence-Jones and serum proteins may be normal. One could guess that this patient had had relatively inactive disease for some time. If she had adequate trauma to cause a fracture, myeloma would satisfactorily explain the whole picture.

DR JACOBSON I would not be so optimistic as Dr Cope about the inactivity of the disease. About 40 per cent of the cases of myeloma have normal serum proteins. About 99 per cent have elevated serum globulin. This patient's globulin was repeated and was low. She had a low formol-gel test. This is the first case of multiple myeloma that I know of in this hospital with a normal globulin.

definitely established. It has been pointed out elsewhere<sup>2</sup> that the long, unsettled and unsatisfactory experience with chaulmoogra oil dictates that considerable caution be exercised in ascribing antileprotic qualities to any drug. The final judgment must await the test of time, which the Carville workers place at five to ten years or possibly even longer.

These results in leprosy have important implications in the treatment of tuberculosis. It is of interest that the drugs that have proved effective in leprosy have been all but abandoned in the treatment of tuberculosis since the introduction of streptomycin. This was due mainly to the toxicity of these drugs and the relatively small benefit apparently derived from them. On the other hand, streptomycin was shown in brief trials to give a temporary improvement in leprosy for only a few weeks and later had no further beneficial effects at a time when the toxic effects of the drug began to occur. For that reason streptomycin has not been widely used in leprosy, which is in contrast to its relatively successful and widespread use in the treatment of tuberculosis. The results of sulfone therapy in the treatment of leprosy should lend encouragement to renewed and more persistent efforts to apply these or similar agents in the treatment of tuberculosis either alone or in conjunction with streptomycin or other effective antibiotics that may become available.

#### PROFESSOR NEUBURGER IN AMERICA

PROFESSOR Max Neuburger, the world-renowned historian of medicine, who on December 8, 1948, will celebrate his eightieth birthday, has arrived in this country, where he plans to spend the years of his retirement. It is fitting that the medical profession send him greetings and take cognizance again of the illuminating contributions of this distinguished scholar.

In 1893 Neuburger received the doctorate of medicine from the University of Vienna, where he had been influenced by such teachers as Billroth,

Meynert, v. Brücke, Nothnagel, Fuchs and Politzer. The title of extra professor of the history of medicine was conferred upon him in 1904 and in 1912 he became titular professor. The University of Vienna honored him with the degree of Doctor of Philosophy in 1917. From 1917-1938 he was professor, founder and director of the Institute of Medicine and Historical Museum at the University of Vienna. Since 1939 he has been a member of the staff of the Wellcome Historical Medical Museum in London, England, and during these years he has published papers on the relations between British and German medicine.

Forty-two years ago, Neuburger's *Geschichte der Medizin* was published in Stuttgart. Through the interest of Sir William Osler the book was translated into English by Ernest Plavfair and was published in 1910 by the Oxford University Press. Osler expressed the thought that the work was particularly useful to English and American students.

Fielding Garrison called Neuburger the greatest philosophical historian of medicine, and Sigerist pointed out that Neuburger's book, monographs and articles were of full significance for our own day. These carefully weighed opinions were justified for at least two reasons: medical history as presented by Neuburger revealed itself as a pulsating living phenomenon supplementing thereby the then current approach, which focused attention upon the philologic analysis of historical texts, and developments in the history of medicine were now being treated by setting them into the background of general history and within the *Kulturgeschichte* with which they ordinarily blend.

Neuburger is unquestionably one of the pivotal figures in the history of medicine today. His writings exhibit high qualities of expansive, critical and well balanced thought. A few excerpts, which are applicable to present-day medical philosophy, from his masterful *History of Medicine* are pertinent.

The economic requirements of the human intellect necessitate a grouping of isolated facts from different points of view. The thirst for knowledge renders imperative a clearer insight into the laws governing natural phenomena. Biological research, cosmology and dialectics were all points on the circumference of a circle, the starting-point being taken at will.

It is neither doctrines nor knowledge which raise the Hippocratic creed to the highest pinnacle of Greek medi-

outbreaks of the disease from assuming major proportions England, in this respect, may now be compared to a city that abandons fireproof building construction because of its fire-fighting equipment that should, under normal conditions, hold in check those conflagrations that are likely to occur

## PROGRESS IN THE TREATMENT OF LEPROSY

THE recently published report of the United States Public Health Service workers on their latest results with the chemotherapy of leprosy<sup>1</sup> is the most encouraging of any thus far recorded and holds out high hopes for the eventual eradication of this ancient scourge. These results are the reward for perseverance and for painstaking efforts in the face of many disappointments that might easily have resulted in discouragement and the abandoning of the project.

Included in the report from the Leprosarium at Carville, Louisiana, are the results of therapy with the sulfone drug in 371 patients of whom 317 were treated with promin or diasone for varying periods up to six years. In the rest, the treatment was abandoned for various reasons but only in a very few cases was this due to failure to tolerate the drug. Severe toxic reactions were encountered, but in most cases it was possible to maintain therapy by adjusting the dose and method of administration. It was found, for example, that promin could not be tolerated in adequate doses when given by mouth. A change to intravenous injections permitted the continuation of therapy with favorable effects. It was usually necessary to start with a daily dose of 1 gm and then to increase the amount until 5 gm daily was given, and this gave the most consistently good results with a minimum of toxic effects.

The most frequent toxic manifestation encountered was a slow destruction of the erythrocytes. This complication could not be avoided, but its effect was counteracted by discontinuing treatment for one week after two weeks of daily intravenous injections. This resulted in fewer and milder types of toxic reactions and permitted a restoration of the blood cells and hemoglobin lost through the hemolytic action of the drug. Transfusions were not used,

and the administration of iron and liver extract was seldom found necessary. Diasone had the advantage of being less toxic than promin by oral administration, but otherwise it gave similar untoward effects. Dosage of this drug had to be increased gradually until the patient built up a tolerance, and most patients were eventually able to take 0.3 gm three times a day. With this drug, rest periods of two weeks every two months proved advisable, and liver extract and iron were sometimes needed to counteract the anemia.

That these efforts and the toxic effects encountered were justified is evidenced by the results. Only patients with lepromatous leprosy and mostly with far-advanced disease were subjected to the sulfone therapy, and the drug worked slowly, but the therapeutic effects were better than those obtained from any previous treatment tried at the Carville Leprosarium. Definite objective improvement seldom became manifest before six months of treatment, but thereafter it was progressive. The percentage of patients improved was in direct proportion to the duration and intensity of the treatment. After six months almost 25 per cent of the patients showed some improvement, after one year this percentage increased to 60, after two years to 75 and after three years to almost 100 per cent, and this was independent of the extent and stage of the disease when the treatment was undertaken. The percentage of bacterioscopically negative smears among treated patients was also in direct proportion to the duration of the treatment. During the first year, practically all the cases remained bacilliferous, but after four years of continuous intensive treatment the incidence of negative reports exceeded 50 per cent.

Of the entire group, 38 patients have been discharged with "arrested" disease, representing 12 per cent of all the patients treated with promin or diasone. During 1946, the number of patients discharged with arrested disease was more than double that of the annual average for the ten years prior to the institution of sulfone therapy and the number of deaths was less than half the average of the previous years.

Faget and Erickson<sup>1</sup> emphasize the fact that the ultimate value of sulfone therapy in leprosy is not

cine and even make it the well-spring of medical science for all time it is the conception of the medical vocation and the method of medical thought and action, true now as then

On the heels of the conqueror with his rude soldierly virtues follows the ruler with his love of luxury and his aspiration towards refinement of manners and customs. This historical law finally compelled even the empress of the earth, invincible Rome, to lay down her arms before a yet more powerful sovereign in the shape of Greek culture.

The essence of Galenism, as contrasted with Hippocratism, consists in giving the physician, through general principles, a reliable guide for his procedure in any individual case.

Honored throughout the world for his scholarly achievements Professor Neuburger may be heartened to learn that American students and physicians recognize the salutary lesson of his life in terms of modesty, patience and dignity. We sincerely wish him continued good health and the spirit and energy to pursue his invaluable labors.

#### STORROW HOUSE

THE Massachusetts General Hospital has announced the opening on August 9, 1948, of Storrow House, with ward, semi-private and private accommodations for convalescent patients. The conditions for admittance are reasonable patients must be ambulatory to the extent of being able to go to meals and they must be persons who are strictly convalescent or simply in need of rest. No terminal or mental patients or alcohol or drug addicts are to be accepted.

Storrow House, a stately mansion situated on a hilltop in Lincoln, Massachusetts, within twenty miles of Boston, was the country home of the late Mrs. James J. Storrow. Fulfilling the wishes of his mother, her son, James J. Storrow, Jr., has presented the house and estate to the Hospital for the purposes outlined above. It is a source of gratification to the recipients of her generosity that Mrs. Storrow's benefactions have continued in this manner after her death.

## TRANSTRACHEAL ANESTHESIA FOR BRONCHOSCOPY

DWIGHT E. HARKEN, M.D.,\* AND ARNOLD M. SALZBERG, M.D.†

BOSTON, MASSACHUSETTS, AND PATERSON, NEW JERSEY

**B**RONCHOSCOPY contributes greatly to the diagnosis and treatment of intrathoracic disease. It is at once apparent that proper anesthesia serves the interest of both the bronchoscopist and the patient.

In a search for the most satisfactory anesthetic technic, the various methods of administering topical agents have been explored, the gamut of general anesthetics has been run, and a series of bronchoscopic and esophagosopic examinations have been conducted under bilateral vagus-nerve block. The technic described below appears to us to serve best the patient and bronchoscopist. The safety of this method is adequately established by experience with more than 1000 patients given tracheobronchial anesthetics.

For many years in the clinic of the late Tudor Edwards at the Brompton Hospital in England, it has been the custom to inject 5 minims of 20 per cent cocaine solution by means of a needle through the skin and cricothyroid membrane into the trachea.<sup>1</sup> This has been used both in bronchography and bronchoscopy. The technic that we have evolved is based on this maneuver but appears to us to have three advantages. The first advantage is derived from a large quantity of dilute agent that gives more complete surface coverage. The second depends on the administration of this agent in two injections, thus producing anesthesia of the main bronchi as well as the trachea. The final advantage accrues from the fact that the patient is in the dorsal decubitus position during the injection.

The simple equipment is illustrated in Figure 1.

### PROCEDURE

The preoperative medication consists of 0.09 gm. of pentobarbital sodium by mouth one and a half hours before bronchoscopy and 0.06 gm. of codeine sulfate by mouth one hour before the procedure.

\*Assistant professor of surgery, Tufts College Medical School, visiting surgeon in thoracic surgery, Boston City Hospital, Mount Auburn Hospital and Malden Hospital; consultant in thoracic surgery, Veterans Administration Hospital, Rutland Heights, Massachusetts, and Chelsea Naval Hospital.

†Senior intern in surgery, Medical College of Virginia Hospital, Richmond, Virginia; formerly resident in surgery, Veterans Administration Hospital, Rutland Heights, Massachusetts.

Ten or fifteen minutes before the intratracheal anesthetic is administered, the lips, mouth and pharynx of the patient are sprayed with 2 per cent pontocaine hydrochloride (dimethylaminoethyl-p-N-butylaminobenzoate) by means of an ordinary atomizer. This means that approximately 3 minims of 2 per cent solution is administered in three

sprays to the zones indicated. The patient is instructed to inspire deeply as the nebulizer is directed toward the back of the tongue and oropharynx.

Next, under aseptic technic with the patient on his back and the head hyperextended the anterior aspect of the neck is cleansed with 70 per cent alcohol. The cricothyroid membrane is identified with the gloved finger in the midline, between the cricoid and thyroid cartilages (Fig. 2). The skin and subcutaneous tissues are infiltrated with 2-cc of 2 per cent procaine hydrochloride. Two 2-cc ampoules of sterile pontocaine hydrochloride,

### PROCEDURE

The preoperative medication consists of 0.09 gm of pentobarbital sodium by mouth one and a half hours before bronchoscopy and 0.06 gm of codeine sulfate by mouth one hour before the procedure.

\*Assistant professor of surgery, Tufts College Medical School, visiting surgeon in thoracic surgery, Boston City Hospital, Mount Auburn Hospital and Malden Hospital; consultant in thoracic surgery, Veterans Administration Hospital, Rutland Heights, Massachusetts, and Chelsea Naval Hospital.

†Senior intern in surgery, Medical College of Virginia Hospital, Richmond, Virginia; formerly resident in surgery, Veterans Administration Hospital, Rutland Heights, Massachusetts.

Ten or fifteen minutes before the intratracheal anesthetic is administered, the lips, mouth and pharynx of the patient are sprayed with 2 per cent pontocaine hydrochloride (dimethylaminoethyl-p-N-butylaminobenzoate) by means of an ordinary atomizer. This means that approximately 3 minims of 2 per cent solution is administered in three

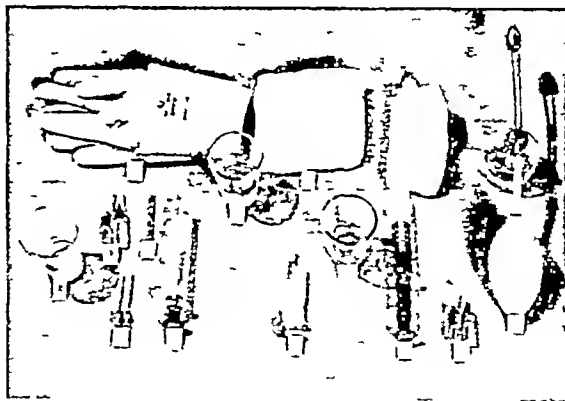

FIGURE 1. Equipment Used for Transtracheal Anesthesia. (1) Gloves. (2) Saline medicine glass. (3) Ampoules of pontocaine. (4) File. (5) Two 18-gauge needles. (6) Syringe for pontocaine. sprays to the zones indicated. The patient is instructed to inspire deeply as the nebulizer is directed toward the back of the tongue and oropharynx.

Next, under aseptic technic with the patient on his back and the head hyperextended, the anterior aspect of the neck is cleansed with 70 per cent alcohol. The cricothyroid membrane is identified with the gloved finger in the midline, between the cricoid and thyroid cartilages (Fig. 2). The skin and subcutaneous tissues are infiltrated with 2-cc of 2 per cent procaine hydrochloride. Two 2-cc ampoules of sterile pontocaine hydrochloride,

each containing 20 mg of the agent, are opened, and 3 cc of this solution is diluted with 6 cc of sterile isotonic saline solution. This provides 9 cc of a 0.3 per cent pontocaine solution and is aspirated into a 10-cc syringe, through an 18-gauge needle. The needle is then directed through the skin in the infiltrated zone, and through the cricothyroid membrane into the trachea. The intratracheal position of the tip of the needle is verified by the aspiration of air into the syringe. Half of the solution is then quickly injected into the trachea, and the needle is immediately withdrawn. An alcohol sponge is firmly pressed over the injection site, for the patient will immediately cough. With the firm

(4.5 cc) is instilled through the cricothyroid membrane. Again, the alcohol pressure sponge is placed over the injection site, the patient is raised to a sitting position, leaned toward the side of principal disease and again instructed to cough. Generally, it has been found that anesthesia is fairly complete throughout the trachea down to the carina, and the patient must be encouraged to cough and expectorate the agent. He is then returned to the dorsal decubitus position and is ready for the bronchoscopic procedure.

After bronchoscopy, the patient is allowed nothing by mouth for three hours lest he aspirate material into the anesthetized tracheobronchial tree.

### DISCUSSION

In view of the small quantity of pontocaine employed (30 mg), the danger of overdosage is probably more theoretical than real, however, sensitivity is possible, since a reaction to four drops of 0.5 per cent pontocaine solution has been reported. Pentobarbital sodium is used in the preoperative medication for prophylaxis against pontocaine reactions. Barbiturates appear to increase tolerance to the anesthetic agent, without reducing efficiency, and their employment before pontocaine anesthesia for bronchoscopy is advised. In addition, it has seemed well to have immediately available a quick-acting barbiturate for intravenous use—0.5 gm of sodium phenobarbital in a 10-cc solution seems adequate for this purpose.

The anesthetic agent is obtained in the form of ampoules of pontocaine hydrochloride, 1 per cent solution (20 mg in 2 cc), prepared for spinal anesthesia. Three cubic centimeters of this solution diluted with 6 cc of isotonic saline solution provides 9 cc of 0.3 per cent solution, which is adequate for tracheobronchial anesthesia. We believe that the large volume of dilute solution is highly advantageous, since it allows more complete surface coverage. Administration in two doses, as described above, is important, for coughing renders the first injection ineffective distal to the carina, however, the second injection gravitates to a lower level because of the prior anesthesia.

It will be noted that both injections are administered with the patient in the dorsal decubitus position. This position renders impossible an accident inherent in the intratracheal instillation of drugs in the upright or sitting position. When a drug is injected into the trachea with the patient sitting upright, regardless of the method, there is always the danger that the patient's position and particular anatomic configuration of the right lower bronchial tree will allow the direct gravitation of the drug to the dependent alveoli. The toxic manifestations of such an accident are similar to the intravenous injection of the drug. The administration of the anesthetic agent by the direct needle injection into

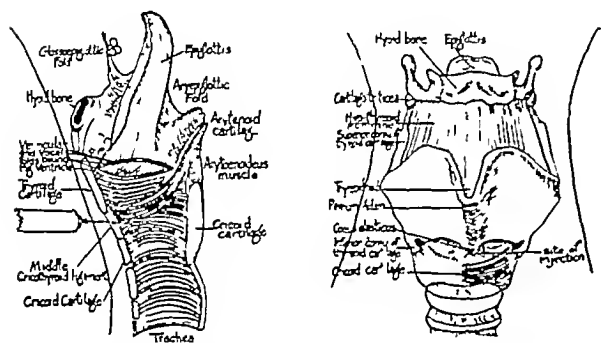

FIGURE 2 *Sagittal and Ventral Aspects of the Laryngeal Anatomy, to Illustrate the Site of Injection*

pressure maintained, the patient is at once instructed to sit up, and coughing is again encouraged. Tracheal secretions are coughed into an emesis basin. The patient is then returned to the dorsal decubitus position and allowed to remain at rest for approximately five minutes. This recess serves three purposes: it allows time for the agent to anesthetize the upper respiratory tract, an opportunity is afforded to explain the subjective symptoms of bronchoscopic anesthesia and examination (it is essential that the patient be reassured that although he has no sensation of air passing in and out of the trachea and pharynx he is actually breathing adequately), and finally, this interval provides an opportunity to watch the patient for drug toxicity or idiosyncrasy. As a safeguard against such a susceptibility 0.5 gm of sodium phenobarbital in 10 cc of water should be available in a syringe ready for intravenous administration. In addition, epinephrine and caffeine sodium benzoate should be at hand in the event of cardiac or respiratory failure. Of course, oxygen should be immediately available in the operating room. Actually, under the outlined conditions, the dangers are virtually negligible.

In a second tracheal injection similar to the first, the remainder of the dilute pontocaine solution

the trachea with the patient supine obviates this danger

A few simple comments about the equipment may be helpful. In Figure 1, two 18-gauge needles may be noted next to the saline medicine glass. The first needle is used for aspiration of 3 cc of 1 per cent pontocaine solution from the ampoules, its subsequent dilution and the first tracheal injection. After withdrawal from the trachea, this needle is discarded as contaminated, and the second needle is used for the second injection. When sterile pontocaine has not been obtainable, we have used 1.5 cc of the conventional pontocaine 2 per cent topical solution, diluted, of course, to 9 cc. This necessitates the inclusion of a third needle for aspiration and dilution of the unsterile solution. Otherwise, the routine is similar, however, if one is to use an unsterile solution, great care must be exercised to avoid leak or injection of this solution in the needle tract between the skin and tracheal lumen.

Though there are theoretical complications, discussed below, the actual complications in the course of more than 1000 cases of tracheal anesthesia have been limited to 3 patients, who had superficial cellulitis of the soft tissues about the site of injection. One resolved spontaneously, and the others required 1-cm skin incisions for drainage. These minor complications occurred more than five years ago, before adequate attention was given to pressure on the injection site and to the prevention of subcutaneous emphysema produced by air leak through the needle tract on coughing.

There are, of course, a number of possible dangers inherent in the technic described above. Often, our colleagues have asked about the dangers of infection spreading in the fascial planes. This has not occurred, and experience seems to justify our

lack of concern over this complication. Another conceivable complication—namely, that of injecting the solution under the tracheal mucosa—does give us some concern. This might produce obstruction to the airway and must be carefully avoided by verification of the position of the point of the needle, by the aspiration of air before injection and by the immediate removal of the needle after the solution has been quickly injected. There have been no tuberculous sinuses even though the method has been extensively used in open cases of tuberculosis. However, we should not elect to use this method in the presence of extensive tuberculous disease of the larynx and upper trachea. There has been no bleeding from an aberrant thyroid isthmus.

Finally, the applications or limitations of this form of anesthesia in bronchoscopy for foreign-body removal are contingent upon the position of the foreign body itself.

#### SUMMARY

A method of administering a dilute pontocaine solution for bronchoscopic anesthesia via the cricothyroid membrane directly into the trachea through a needle is described.

Technical details and the rationale of the maneuvers are outlined.

Theoretical and actual dangers are given consideration. The safety of the method is supported by experience in more than 1000 patients.

The value to patient and physician of a safe anesthetic technic that minimizes the discomfort of bronchoscopy is stressed.

## COEXISTING TUBERCULOUS AND MENINGOCOCCAL MENINGITIS\*

## Report of a Case

CAPTAIN EDGAR ALSOP RILEY, M C, A U S †

**M**ENINGITIS due to a simultaneous mixed infection is relatively rare. Neal<sup>1</sup> reviewed 3178 cases of meningitis and found that 26, or 0.8 per cent, were due to mixed infections. Unfortunately she did not break down these 26 cases into the different bacterial combinations that were present. Tripoli<sup>2</sup> studied 468 cases of bacterial meningitis and found 2 cases of mixed infection, an incidence of approximately 0.4 per cent. In a more recent study Hertzog<sup>3</sup> reviewed 377 cases of fatal meningitis with special reference to the bacterial diagnoses and collected 5 cases of mixed infection, or an incidence of 1.3 per cent.

Cases of tuberculous meningitis combined with a suppurative acute bacterial meningitis are even more unusual. Lemieux et al.,<sup>4</sup> in a review of the literature between 1900 and 1944, found only 20 reported cases of an associated meningococcal tuberculous meningeal infection. In the present review, an additional number of mixed cases of tuberculous meningococcal meningitis were discovered in the literature that had apparently not been found by those authors. Pipirs,<sup>5</sup> cited by Key,<sup>6</sup> studied 46 cases of mixed meningeal infection reported between 1896 and 1927 and found that the tubercle bacillus predominated as the primary organism. Cunningham<sup>7</sup> quotes Chalier and Guichard<sup>8</sup> as reporting in 1931 about 50 cases of combined tuberculous and meningococcal meningitis.

Regardless of the exact number of cases of combined tuberculous and suppurative infections of the meninges that have been reported, it was thought that the combination was unusual enough to justify presentation of the following case of a combined tuberculous and meningococcal meningitis.

## CASE REPORT

A 26-year-old man was admitted to the medical service on January 30, 1945, with the diagnosis of nasopharyngitis. About 4 days previously the patient had mentioned to a friend that he was suffering from a severe headache. At sick call on the following day he was seen by a medical officer, who believed that he had an upper respiratory infection, prescribed aspirin and returned him to duty. On January 28, the patient had again gone to sick call because of persistent headache and because he felt too sick to do duty. He was afebrile. The medical officer again believed that this soldier was suffering from nasopharyngitis and recommended symptomatic therapy. On the following day, however, the patient was admitted to the hospital complaining bitterly of a severe headache, which seemed to be localized to the base of the skull. He was rational, but was so acutely ill that a thorough history was not attempted. He admitted vomiting twice.

Physical examination revealed a well developed, well nourished man who was co-operative and rational. There was marked rigidity of the neck, the patient complained

bitterly when his head was flexed upon his neck. Neurologic examination revealed positive Kernig and Brudzinski signs, with a bilateral negative Babinski reflex. The remainder of the physical examination was negative.

The temperature was 98.8°F, the pulse 80, and the respirations 18.

A lumbar puncture was immediately performed, and several cubic centimeters of slightly cloudy fluid were removed for examination. A manometer was not available at the time for accurate determination of the spinal-fluid pressure, but it appeared abnormally high. Examination of the fluid revealed 774 white cells per cubic millimeter, with 54 per cent neutrophils and 46 per cent lymphocytes. The total protein was 270 mg per 100 cc. Sugar was not found in the sample. A diagnostic stain of the spinal fluid was made, and two gram-negative diplococci organisms suggestive of *Neisseria* were seen. Spinal-fluid culture was carried out, and at the end of 24 hours a luxuriant growth of *Neisseria intracellulare* was present. A malarial smear was taken, since the patient had seen service in Sicily and Italy, but was negative.

The patient was immediately started on a therapeutic course of sodium sulfadiazine intravenously and fluids parenterally. During the day he was rational but complained of nausea and had frequent episodes of projectile vomiting.

On the morning of the following day the temperature was 101.6°F, the respirations 16, and the pulse 54. On that afternoon, intravenous administration of sulfadiazine was discontinued, and he was put on a dosage schedule of 1 gm. of sulfadiazine orally accompanied by 2 gm. of sodium bicarbonate every 4 hours. At 8:00 p.m. the temperature was still 101.6°F, and 20,000 units of penicillin intramuscularly was ordered every 3 hours. During the day the patient appeared rather irritable and mentally hazy and continued to complain of a stiff neck.

On the morning of the following day the temperature was 99.6°F, but by noon it had climbed to 101.2°F. A lumbar puncture was done and several cubic centimeters of cloudy fluid under elevated pressure were removed. Examination of the fluid disclosed 441 white cells per cubic millimeter, but no differential count was obtained. A smear for organisms was negative, as was a culture at the end of 24 hours. The temperature dropped to 99°F by evening, but again climbed and at 3:00 a.m. on February 3 was 102°F. During the night he was incoherent and experienced a severe chill.

During the entire next day, the patient was mentally confused. He developed increasingly pronounced signs of meningeal irritation and during the morning had a severe clonic convulsion involving the right side of his body. During this attack, his pupils failed to react to light or accommodation and his left eye rotated inward. His temperature continued to climb and by midnight had reached 103.6°F.

On February 4 he continued to be restless and incoherent and had to be catheterized every 8 hours. Intravenous administration of fluids was maintained throughout the day.

On the following day the patient appeared much worse, developed Cheyne-Stokes respirations and was comatose throughout the morning. Doses of aminophylline and caffeine sodium benzoate relieved his respirations considerably. A lumbar puncture was done, and several cubic centimeters of opalescent fluid were removed. Examination of the fluid revealed 441 white cells per cubic millimeter, with 4 per cent neutrophils and 96 per cent lymphocytes. The sugar was 136 mg per 100 cc, and the chloride 473 mg per 100 cc. After the fluid had stood for 10 minutes, a delicate fibrin pellicle formed, but search of a stained smear revealed no acid-fast organisms, and a 24-hour culture for pathogens was negative. At the time this lumbar puncture was done, 10,000 units of penicillin was injected intrathecally, but after a report of the spinal fluid was obtained, it was considered useless to continue intrathecal medication on subsequent taps, and penicillin was discontinued. An x-ray film of the chest taken at the bedside showed some generalized increase in density of the left lower lobe.

\*From the Medical Service, Letterman General Hospital, San Francisco, California.  
†Assistant resident on Chest Service, Bellevue Hospital, New York City.

During February 6 the patient's condition remained about the same. He showed occasional moments of rationality but by afternoon had lapsed into complete stupor. Neurologic survey revealed loss of deep and superficial reflexes bilaterally with a positive bilateral Babinski sign. The Kernig and Brudzinski signs continued to be present. The pupils failed to react to light or accommodation, and the left eye continued to rotate inward. During the day he received fluids, sulfadiazine, oxygen and caffeine sodium benzoate intravenously. Examination of the blood showed a red-cell count of 4,410,000 and a white-cell count of 13,000, with 78 per cent neutrophils, 12 per cent lymphocytes and 5 per cent monocytes.

During the following day the patient remained comatose. Because of the high, fluctuating temperature a malaria smear was done and was found to be positive for *Plasmodium vivax*. A lumbar puncture during the day revealed 230 white cells per cubic millimeter, with 99 per cent lymphocytes. A very definite, fine fibrin pellicle formed within an hour of standing. Since quinine or atabrine for intravenous or intramuscular use was not available at that time, the patient was given 0.4 gm of atabrine that evening by rectum. On the next day quinine dihydrochloride was obtained, and large doses were given intravenously and intramuscularly every 6 hours. By 6:30 p.m. on February 9 the patient's condition became terminal, and his temperature continued to rise during the night, reaching 107.4°F by 4:00 a.m. At 6:00 a.m. on February 10 he ceased to breathe.

At autopsy the body was that of a fairly well developed man, revealing marked rigor mortis. The pupils were round and slightly unequal. When the pleural cavity was entered the lungs retracted, and no excess pleural fluid was observed. The lungs showed no pertinent disease on either gross or microscopic examination, and no tuberculosis was found. Examination of the spleen was essentially negative, and despite multiple sectioning, no lesions were noted. Examination of the liver was also negative.

On examination of the brain the external appearance of the dura showed no abnormalities. It was incised and reflected, revealing a very markedly congested vessel over both cerebral hemispheres. In addition, there was a small amount of yellow material about the blood vessels, and occasional small white foci, approximately 1 mm in diameter, were seen in the pia arachnoid. The brain was marked in the usual manner. It was of the usual size and shape, but slightly decreased in weight, which was 1280 gm. Over the base of the brain, there was a gelatinous, cloudy exudate, which was very abundant and which became yellow, opaque and purulent about the optic chiasm. This exudative process also clouded the leptomeninges covering the cerebellum. The multiple white, minute foci noted over the cerebral hemispheres were very numerous about the base of the brain and over the cerebellum. When the leptomeninges were dissected free, it was noted that they seemed to be contained within the meninges. Multiple coronal sections throughout the brain revealed some dilatation of the lateral and third ventricles. There was also a slight thinning of the cerebral cortex, however, there was no evidence of molding of the cerebellum about the brain stem. The superior portion of the caudate nucleus on the left contained red, softened areas measuring 0.8 cm in diameter. The superior portion of the temporal lobe on the right contained a very soft area immediately adjacent to the sylvian fissure. The meninges were thickened in this area, and the superior portion of the temporal lobe was adherent to the undersurface of the parietal lobe. There was no yellow discoloration about the border of the region, and no evidence of hemorrhage into it. The tissue in this region was white, soft and friable, and no sharp line of demarcation delimited this area from the surrounding brain tissue. In a number of areas throughout the brain, small congested vessels were visible, and petechiae were suggested. There was no evidence of gross hemorrhage or necrosis in the thalamus or brain stem.

On microscopic examination of the brain many of the blood vessels of the leptomeninges were surrounded by a cuff of chronic inflammatory cells, chiefly lymphocytes and mononuclear cells. There was a fairly diffuse infiltration of the leptomeninges by chronic inflammatory cells. In some areas, often perivascularly, there were foci of caseous necrosis. Tubercle-like lesions were noted with large numbers of epithelioid cells and scattered, multinucleated Langhans' giant cells. Acid-fast stains of these areas revealed scattered

acid-fast bacilli identical morphologically with tubercle bacilli. The chronic inflammatory infiltrate was also noted about the vessels in the Virchow-Robin spaces and in some areas deep within the brain substance. There was a fairly generalized congestion of the blood vessels of the brain, and in some areas, perivascular extravasation of red cells was present. The pineal body was surrounded by a similar inflammatory process. In a rare area, the peripheral substance of the brain was involved in a caseous necrosis for a short distance beneath the pia mater. However, the appearance was that of an extension of the meningeal process into the brain rather than vice versa. No true tuberculoma was noted. The softened area described grossly in the temporal lobe microscopically was composed of brain containing foci of hemorrhage and fragmentation of the brain substance with a few scattered polymorphonuclear leukocytes. The choroid plexus contained numerous small, round, calcific bodies, and a few of the vessels were surrounded by a cuff of lymphocytes. However, no marked inflammatory involvement or caseous necrosis was noted similar to that seen in the meninges. Occasional ganglion cells showed evidence of mild degenerative changes, with swelling and rounding of the cytoplasmic borders. There was a congestion and generalized slight increase in the glial cells throughout the brain.

Culture of the heart's blood revealed no growth.

A gram stain of the right lower lobe of the lung disclosed no organisms. On culture a nonhemolytic *Staphylococcus aureus* and a *Streptococcus viridans* were observed.

No malaria parasites were seen on a smear of the spleen.

A smear of the brain abscess demonstrated no organisms. Culture showed an alkaligenes bacillus, gram-positive cocci in chains and groups were overgrown by the gram-negative bacilli. On guinea-pig inoculation acid-fast bacilli were recovered from an inguinal lymph node and spleen.

On March 20 an autopsy of a guinea pig inoculated 38 days previously was positive for lesions typical of tuberculosis. Smears from the lesions showed the presence of acid-fast bacilli.

## DISCUSSION

This case was of unusual interest. What at the onset appeared to be an uncomplicated case of meningococcal meningitis terminated fatally with a tuberculous infection of the meninges and was further complicated by the recrudescence of a malarial infection that the patient had undoubtedly contracted during his service in Sicily and Italy. Because of the comparative rarity of a combined tuberculous and suppurative meningeal infection, it was thought of interest to review the literature. The cases reported in the medical literature since 1911 are presented in Table I.

A review of this table shows that most of these case reports are from the foreign literature. The case presented above is the first reported from American sources, and is approximately the thirty-fourth case of its type in the literature. Since meningococcal meningitis has been found in many series to be the most common bacterial type of meningitis, it is not surprising that cases of tuberculous meningococcal meningitis predominate.

The record in this case reveals considerable similarity with those in the other reported cases. The patient entered the hospital with the classic signs and symptoms of meningitis. Although, unfortunately, there is no record of any bacterial cultures taken from the nasopharynx, it can probably be assumed that this was the initial focus from which dissemination to the meninges occurred. The

spinal-fluid findings were certainly compatible with a meningococcal meningitis, and it is possible that at the time of onset the patient had a pure meningococcal infection. In retrospect however, there is one finding that might be significant in view of the patient's subsequent course. This is the fact that despite the acuteness of the infection, only 54 per cent of the white cells were neutrophils. This is almost the same ratio of lymphocytes to neutrophils as was found by Fiddes<sup>34</sup> in a case of

mixed tuberculous meningococcal meningitis in a fourteen-month-old baby. That this relative lymphocytosis in the face of a suppurative meningeal infection may be of significance is further strengthened by the findings of Claude et al.<sup>18</sup> These authors reviewed the literature and stated that in most cases an acute polymorphonuclear response in the spinal fluid is replaced by a lymphocytosis. Moritz,<sup>31</sup> in the report of a case of mixed tuberculous and Friedländer meningitis, also points out that the duality of the infection may alter the spinal-fluid findings. However, without some clinical findings to support the diagnosis of a tuberculous meningitis, it would be misleading in many cases to place too much emphasis on these findings alone.

After the institution of sulfadiazine therapy supplemented later by penicillin, the patient failed

to respond clinically but continued a downhill course, despite the fact that, after three days of sulfadiazine therapy, smear and culture of specimens of the spinal fluid were negative for the meningococcus. It was not until after the patient had shown progressive mental deterioration and central-nervous-system damage that another lumbar puncture revealed the pathognomonic fibrin pellicle and the characteristic cell count and chemical findings of a tuberculous meningitis.

As in the majority of other reported cases of combined tuberculous and suppurative meningitis, the failure of the patient to respond to specific therapy was the clue that led to the suspicion that perhaps this was a double infection. Certainly, with no obvious manifestations of an active tuberculous process elsewhere in the body, there was no reason to suspect a tuberculous infection earlier. Many of the available case reports emphasize the fact that the diagnosis of a mixed infection can only be made bacteriologically and that the suppurative phase does not alter the progressive characteristic course of the tuberculous infection or establish any marked deviation from the usual clinical pattern. Since there is apparently no characteristic clinical picture of the mixed type of infection, it is possible that a certain number of such cases are missed, owing to the fact that complete bacteriologic studies are not always carried out because the possibility of a combined infection is not considered.

The central-nervous-system pathological findings in this case were characteristic of a pure tuberculous meningitis. In almost all the other reported cases in which chronologically the tuberculous phase appears to have been superimposed upon the suppurative phase, the pathological findings have been those of a tuberculous infection alone. These findings certainly suggest that the tuberculous invasion is secondary to the suppurative phase, although Moritz<sup>31</sup> believes that the pathological findings of the two types of meningitis are not sufficiently distinct to enable any conclusions to be drawn regarding the primary infection. That the pathological changes secondary to the acute suppurative phase may be masked by the changes resulting from the tuberculous infection is suggested in the findings of a case of mixed tuberculous pneumococcal meningitis reported by Achard and Horowitz.<sup>22</sup> At post-mortem examination of the brain, a typical basal meningitis most marked in the region of the fourth ventricle was present. The arachnoid was thickened, opaque and milky in appearance, areas of caseation were present in the floor of the fourth ventricle, and no findings characteristic of a suppurative meningitis were observed. However, both pneumococci and tubercle bacilli were cultured from spinal fluid taken from the fourth ventricle, and both organisms were found by smear and culture in adjacent areas of

caseation The case reported by Fiddes<sup>44</sup> is interesting in that two distinct types of exudate were present

On the ventral surface of the cerebellum and stretching forward to the pons was a thick greenish-yellow purulent exudate. Covering the midbrain and crura cerebri and running into the cerebral sulci along the vessels was a much thinner, whitish exudate, containing many miliary tubercles especially about the vessels of the Sylvian fissure. There was a great excess of spinal fluid in the ventricles. The brain was fixed and when examined later, both lateral ventricles were greatly dilated and many miliary tuberculomata were seen in their walls

The two different types of exudate described certainly suggest the combined effects of a suppurative and nonsuppurative type of pathologic process. In the findings in the case presented above, however, there was nothing to suggest the presence of a suppurative process, and to quote from the comments made by Colonel Harold L. Stewart, the pathologist, "the histologic findings and demonstration of acid-fast organisms leave little doubt regarding the type of meningitis, at least in the terminal phase."

The pathogenetic problems presented by this case are extremely interesting. Until the publication of the paper by Rich and McCordock<sup>47</sup> from Johns Hopkins in 1933, tuberculous meningitis was generally considered to be the result of hematogenous dissemination of the tubercle bacilli to the meninges. The reason for this was the high incidence of tuberculous meningitis found in association with cases of disseminated hematogenous tuberculosis. Rich and McCordock, however, believed that several factors lent doubt to the hematogenous theory explaining the pathogenesis of tuberculosis of the meninges. Because of these objections, they considered the rupture of a caseous tuberculous focus into the subarachnoid space to be a better explanation of the pathogenesis of tuberculous meningitis. This caseous focus might be in the adjacent vertebra, in the meninges themselves or in the brain or spinal cord. By very meticulous sectioning of the brains and spinal cords of 82 cases of tuberculous meningitis, the authors were able to demonstrate caseous foci in 77 cases and in the 5 cases in which foci were not demonstrated, the examinations were not complete. This work of Rich and McCordock has been repeated and confirmed by other workers. MacGregor and Green,<sup>48</sup> for example, in examining 88 brains and spinal cords from cases of tuberculous meningitis found caseous foci in 74 brains and evidence of tuberculosis of the spine in 4 other cases making a total of 78 cases, or 88.6 per cent. In 59 of these cases, or 67 per cent, it was proved conclusively that the origin of the meningitis was from these caseous foci, and in a further 6 cases it was found highly probable, making a total of 74 per cent. In only 4 cases in this series were caseous choroid tubercles present, and the authors regarded these

choroid-plexus foci as part of the diffuse meningitis and of no pathogenetic significance.

Although the work of MacGregor and Green tends to support the conclusions reached by Rich and McCordock, their findings have not always been substantiated. Ragins,<sup>49</sup> for example, studied 39 cases of tuberculous meningitis and found that in 32 cases (82 per cent) the meningitis resulted from direct hematogenous spread from some focus of visceral tuberculosis found at autopsy. In another series of cases, Engel<sup>50</sup> studied 15 cases of tuberculous meningitis superimposed upon generalized miliary tuberculosis and failed to discover in a single case caseous foci that could be considered the source of the meningeal infection. In all cases the choroid plexi were involved microscopically with an acute tuberculous process with tubercle bacilli present in every case. The author reached the conclusion that infection from the choroid plexus was a more important factor in the pathogenesis than the rupture of a caseous focus into the subarachnoid space.

In the case reported above, the source of the tuberculous meningitis remains a mystery. No visceral focus of tuberculosis was found in any of the organs examined. It was suggested by Colonel Stewart that perhaps some small tuberculoma had been overlooked in the sections of the brain examined and this remains the best possibility. Both Rich and McCordock and MacGregor and Green mention the ease with which a small tuberculoma may be overlooked unless particular care is taken during the sectioning. The former group emphasize the fact that the brain sections should not be more than 3 mm in thickness and that special technics must be employed in many cases to demonstrate tuberculomas that are fresh and not yet encapsulated. In this case no mention was made of the number or thickness of the sections examined or the technic employed.

There were several other possible sites in this case for caseous foci that might have ruptured into the subarachnoid space, but in none of them is the possibility anything but remote. There was no evidence of any active caseous foci in the choroid plexi. It has been mentioned that a vertebral lesion may be the source of a tuberculous meningitis, and in this particular case there is no mention that this possibility was completely excluded by x-ray or pathological examination. However, it is unlikely that such a focus existed since the patient had no complaints suggestive of a vertebral lesion. Crowe<sup>51</sup> has demonstrated that a tuberculous otitis media can be the source of direct meningeal invasion in tuberculous meningitis, but this patient had no complaints referable to his ears and examination of the ear, nose and throat upon admission had been negative. There is one other possibility that was not wholly precluded since a complete examination of the spinal cord was not

performed a spinal-cord tuberculoma that had ruptured into the subarachnoid space, causing a meningitis

Single or multiple tuberculomas of the spinal cord are not common. By 1943 only 93 cases had been reported in the literature.<sup>42</sup> The most comprehensive review of the subject of spinal-cord tuberculomas was published by Thalhimer and Hassin<sup>43</sup> in 1922. These authors collected 67 cases and reported abstracts on 58. As might have been expected, almost every case presented symptoms suggestive of an expanding spinal-cord lesion that, in the majority of cases, was diagnosed clinically as a spinal-cord tumor. The cases of spinal-cord tuberculoma examined at autopsy often revealed microscopical and gross evidence of a localized tuberculous meningitis about the nerve roots, with extension of the caseous process up to and sometimes into the subarachnoid space. In the case reported above, however, because of the lack of any symptoms referable to the spine and especially because of the failure to find any active tuberculous focus elsewhere that could have acted as a feeding lesion, a spinal-cord tuberculoma producing meningitis is unlikely.

The relation between the suppurative and the tuberculous phases of this patient's illness is an interesting one. Certain writers, such as Claude and his co-workers,<sup>15</sup> considered the association coincidental. Moritz<sup>21</sup> believed that the tuberculous infection was primary, even though the tubercle bacillus did not appear in the spinal fluid until the day before death and although the Friedländer bacillus was found after the first lumbar puncture. Lemieux et al.<sup>4</sup> also regarded the suppurative phase of the dual infection as secondary.

Other authors, however, have thought differently. In a case of mixed meningococcal and tuberculous meningitis reported by Schuman<sup>27</sup> in a six-year-old boy who, three weeks before the onset of meningitis, had had an attack of measles, it was believed that the measles had activated a dormant tuberculous lesion of the lung, with a resultant meningitis. In another case of a combined tuberculous meningococcal meningitis reported by Grysez and his associates,<sup>28</sup> the meningococcal infection was considered to have activated a latent tuberculous focus. From the clinical and pathological evidence in this case, this mechanism seems the most likely explanation.

Baum and Amberson,<sup>44</sup> in a study of cases of pulmonary tuberculosis existing concomitantly with bronchiectasis, lung abscess and pneumonia, have demonstrated conclusively that a latent focus can be activated by a suppurative process. "Suppurative disease has been found repeatedly to be responsible for the activation of a tuberculous process, the mechanism most likely being destruction of the capsule with consequent liberation of the tubercle bacillus." If such a mechanism can be

held responsible for the activation of a pulmonary focus, the same mechanism can be held responsible for the activation of a subarachnoid focus, too small to have been demonstrated on sections. The problem of the exacerbation of the old malarial infection is perhaps even more obscure than the problems of pathogenesis raised by the dual meningeal infection.

## SUMMARY

An additional case of coexisting tuberculous and meningococcal meningitis is reported, and the pertinent literature is reviewed.

The pathogenesis of the inter-relation between tuberculous and suppurative meningitis is discussed.

It is hoped that further cases will be reported as they appear.

## PROPHYLAXIS AGAINST ALLERGY

### A Pediatric Program

MAURICE H. SHULMAN, M.D.

BOSTON

THE pediatrician holds a unique position in the field of allergy. To him falls the opportunity of dealing with the patient before the first manifestations of allergy. Therefore, whatever can be achieved in the way of preventive allergy lies within his sphere.

Allergy is defined as an altered reactivity of tissues following the introduction of foreign protein by inhalation, injection or ingestion. The difficulties of taking prophylactic measures in the field of allergy are inherent in its definition. In general, it is only after the occurrence of clinical symptoms that steps are taken to eliminate the offending allergens when possible, or to protect the patient by hyposensitization when indicated. Logically, many symptoms might be avoided by elimination or by guarded exposure prior to sensitization. Present knowledge is such that much foresight can be exercised.

In the evolution of the literature dealing with allergy, many equivocal and some contradictory findings appear. Many data, however, have been well established. Together with advances in clinical experience, this knowledge provides at least the foundation of a plan for prophylaxis.

The inheritance of the tendency to develop allergy is now generally accepted. Repeated observations of most clinicians, regardless of the variation in their figures, force the conclusion that the children of allergic adults will constitute the greatest number of allergic persons in the next generation. It is the purpose of this paper to outline a regime for this group of potentially allergic children by which the danger of sensitization to certain potent allergens may be minimized.

### HEREDITY OF ALLERGY

Vaughan<sup>1</sup> has summarized and evaluated the numerous statistical studies concerning the heredity of allergy. His figures indicate that about 10 per cent of the general population suffer from major allergy and that another 50 per cent have minor allergy. There is an antecedent family history of allergy in from 50 to 70 per cent of allergic patients whereas only 7 per cent of nonallergic people give a family history of allergy. Differences in methods of statistical classification employed by the various writers apparently account for the variation in their figures.

Table 1 illustrates this variation.

Vaughan concludes that there is a hereditary factor in allergy. He estimates that about 75 per cent

TABLE 1 *Types of Allergy in Relation to Positive Family History\**

ALLERGIC MANIFESTATION	POSITIVE FAMILY HISTORY %
Asthma (in children)	40-70
Asthma (in adults)	40-60
Migraine	75-85
Food allergy	68
Eczema	28-76
Urticaria	25-50

\*Adapted from Vaughan<sup>1</sup>

of all children with bilateral allergic inheritance and about 50 per cent of those with unilateral inheritance will eventually develop some type of allergic manifestation. The heavier the inheritance, the greater the number of allergic symptoms and the earlier they will appear in each offspring.

Since the earliest indication of this potentiality lies in the parental history, the importance of determining the presence or absence of allergy in the parents of the newborn by carefully taken case histories becomes evident. The program for the care and feeding of such infants during their first year of life can be guided by such information. Although all children of allergic parents need not become allergic themselves, their potentialities must certainly be reckoned with as a group.

### MECHANISM OF SENSITIZATION

The mechanism of sensitization depends on the type of allergy involved. The inhalants, as the name suggests, occur in the environment of the patient or in the atmosphere, creating sensitization through the respiratory tract. Pollens, ubiquitous and probably uncontrollable, fall into this category. Other inhalants, such as feathers and animal dander, are controllable. Allergens found in food cause symptoms upon ingestion, and these symptoms are alleviated by diet.

The presence of the allergic tendency, whether inherited or acquired, does not result in clinical allergy unless sensitization occurs by exposure to potent allergens. A large part of allergic treatment consists of elimination of offending allergens from the environment or the diet. This clinical procedure has given excellent results. Is it not wiser, then, to avoid exposure, thereby substituting prevention for the need of a cure?

The factor of food allergens is most important at the earliest period of life. Fortunately for this group, the dietary intake is most readily regulated at this time. Adequate infant feeding has two major requirements: normal growth must be maintained, and minimum vitamin and mineral requirements must be fulfilled. These two basic requirements can be met, while, at the same time, the exposure to potent allergens is lessened.

Food allergy has been recognized for many years, but it was not until 1916 that Schloss and Worthen<sup>2</sup> gave the first hint of its mechanics. In their classic paper they proved that foreign proteins are absorbed in unchanged form through the gastrointestinal tracts of normal infants and to a greater degree in those suffering from debility or any form of gastroenteritis. In 1920 Schloss<sup>3</sup> described the hyperacute type of sensitivity to food as evidenced by urticaria, asthma and symptoms of shock. The diagnosis of this condition is commonly made by the parents because of its obvious cause and effect relation. The symptoms are so distressing that the detection of the offending food is never a problem. Another type of sensitivity that brought on gastrointestinal disturbances with vomiting and diarrhea or skin manifestations such as eczema was described by the same author. In 1925 DuBois, Schloss and Anderson<sup>4</sup> reported that enteral absorption of antigenic protein by normal or marasmic infants led

not only to the appearance of a specific precipitin in the blood but also, in many cases, to cutaneous sensitivity. This fundamental work has been repeated by Wilson and Walzer<sup>5</sup> and other investigators.

Schloss and his co-workers<sup>6</sup> stated that the mechanism whereby the body is protected from the continued absorption of appreciable amounts of foreign protein was unknown. This statement still holds true today. They advanced three possible explanations, which continue to be of great interest by some means the gastrointestinal wall becomes impermeable to each newly introduced protein after it has been ingested for a certain length of time, an alteration in the digestive enzymes takes place so that they ultimately become capable of producing complete denaturation, and finally, even though foreign protein is absorbed as such, it may be neutralized by some hitherto unrecognized immune reactions. It has been observed by Rackemann<sup>7</sup> and others<sup>8</sup> that children frequently manifest the first symptoms of hypersensitivity to antigenic substances a few days or weeks after initial exposure. This interval coincides with the development of the antibodies as observed by Schloss and his co-workers<sup>6</sup>. In the average infant this immunologic process is passed over without incident. In the infant with the inherited tendency to hypersensitivity, Schloss and his associates<sup>6</sup> have reasoned that this mechanism may be altered so that the clinical manifestations of allergy result.

### BASIC FOODS IN INFANT FEEDING

The basic foods in infant feeding are milk, egg, wheat, orange juice and fish oil. These foods are added to the diet at varying ages, depending on the fashion of the moment and, to a lesser degree, on the school of thought to which the practicing pediatrician subscribes. Allergists<sup>9</sup> have found these five foods to be the most common sources of allergic manifestations in infants and young children. Laboratory workers have used the same allergens to prove the absorption of undigested protein through the gastrointestinal tract. Thus, there is the rare circumstance of five basic foods, ever-present in infant feeding, that are potent allergens and are readily absorbed unchanged through the mucous membrane of the gastrointestinal tract.

In summary, a large number of infants are potentially allergic by reason of heredity. Five basic food requirements of the infant diet are potent allergens, and these proteins are absorbed unchanged through the gastrointestinal tract. Is it not logical, then, to diminish the potency of these allergens by introducing them into the diet in a denatured form or to avoid them whenever possible?

Milk holds a unique position in the infant diet, unparalleled by any one food in adult life. Hill<sup>10</sup> pointed out that the infant takes enormous quantities of milk in proportion to his weight. He

asserted that nature never intended the infant diet to have so high a protein content as that furnished by cow's milk and that the infant's digestive function is not adapted to this milk.

There are two proteins present in milk the more common offender, as Hill and Pratt<sup>11</sup> have pointed out, is lactalbumin, the second is casein. Anderson, Schloss and Stuart<sup>12</sup> demonstrated the close biologic relation between goat, cow and human casein. This explains why casein-sensitive patients do not benefit when the milk ingested is changed from one type to another. Lewis and Hayden,<sup>13</sup> in 1930, reported a diminution of antigenic properties in heated milk. Ratner<sup>14</sup> supported this view by pointing out the diminished antigenicity of evaporated cow's milk, owing to the prolonged heat applied in evaporation. Because of its method of manufacture, this does not hold true of powdered milk.

Egg allergy in infants and children is relatively common and important. As early as 1907, Gelbke<sup>15</sup> reported marked clinical response to the ingestion of egg. The cases reported were of the immediate, dramatic type, the symptoms developing instantaneously from the slightest contact with egg. This high degree of sensitivity does not represent the most frequent type of reaction. The slow, masked type of reaction is more common. In Vaughan's<sup>1</sup> experience, corroborated by Hill and others, egg appears to cause cutaneous manifestations more frequently than other symptoms.

There are a few cases on record in which egg sensitization appears to have been hereditary. This situation is evidenced by the occurrence of symptoms on the first exposure to this food. These cases are the exception rather than the rule.

Although egg white is the most frequent source of trouble, the egg yolk cannot be considered blameless. Egg white is the most difficult of all proteins to digest completely. Walzer<sup>16</sup> has found that incompletely digested egg protein circulates normally in the blood of some infants after feedings.

There are at least three aspects to the problem of egg as an allergen. Foremost is the prevailing custom of early introduction of egg into the diet of infants. Undigested egg protein circulating in the blood makes sensitization much easier in the potentially allergic infant. The second is the inability to denaturize egg by heat or any other known procedure. The third, and equally important, is the frequency with which egg is used in the preparation of other foods.

Wheat is also an ubiquitous allergen. Less potent than egg, it is also ingested in large quantities at an early age by most infants. Of 63 prepared cereals and infants' foods that contain wheat, 39 convey by their trade names no suggestion of the presence of wheat. Whether or not the allergenicity of wheat is diminished by heat in its preparation is still a disputed point. It is sufficient to say that the early ingestion of wheat together with the failure to recog-

nize its presence in many prepared foods makes this allergen an active one in the infant. Rarely does wheat cause the type of acute symptom complex associated with a potent allergen such as egg.

Fish as an allergen in infancy may seem paradoxical since fish is not often included in infant feeding. When, however, one considers that thirty species of fish are recognized and allowable as the source of *USP* cod-liver oil, its importance becomes evident.

Clinically, fish may cause either an acute or a delayed type of reaction. In the hypersensitive patient the odor of fish may cause asthma. Denaturation here is again difficult. Clinically complete avoidance has been the most expedient course. Since cod-liver oil, or at any rate, vitamins A and D are added to the infant diet at a very early age, care must be exercised in handling this potent allergen.

Another essential in all infant feeding is vitamin C. This is usually added to the diet at an early age in the form of orange juice. Sensitivity to orange juice does occur. Even the artificial coloring added to most oranges has been known to cause allergy. Denaturation by heat is impractical because it destroys the vitamin C content.

#### PROPHYLACTIC TREATMENT OF THE POTENTIALLY ALLERGIC INFANT

The prophylactic treatment of the potentially allergic infant must begin at birth. Every child in this category must be carefully watched for the first sign of an allergic manifestation. Before any symptoms develop, the following procedures are recommended to avoid, whenever possible, exposure to active allergens.

The period necessary for the development of symptoms after the introduction of a new food is not definitely known. The work of Schloss et al,<sup>4</sup> Rackemann<sup>7</sup> and Hill,<sup>10</sup> in addition to personal experience, has prompted the adoption of an arbitrary time of fourteen to twenty-one days as a trial period. Immediate symptoms are detected readily, and such a trial period allows sufficient time for cumulative effect to become apparent.

When the trial period has been passed safely, a food may be considered nonallergenic for the patient under consideration. The next danger lies in the continual daily or even twice daily ingestion of the accepted food. This hazard may be overcome by rotation of diet. For example, if cereal is given daily, there should be a rotation of cereals: wheat one day, rice the next day and oats the following day. Vegetables and meat should also be rotated.

The pediatrician's first concern for any newborn infant is a formula on which the infant can thrive. Evaporated milk is the first choice whenever breast feeding is not feasible. The low antigenicity of the lactalbumin in evaporated milk has been firmly established. Care should be exercised to determine that cow's milk is not first given as a matter of hos-

Since the earliest indication of this potentiality lies in the parental history, the importance of determining the presence or absence of allergy in the parents of the newborn by carefully taken case histories becomes evident. The program for the care and feeding of such infants during their first year of life can be guided by such information. Although all children of allergic parents need not become allergic themselves, their potentialities must certainly be reckoned with as a group.

### MECHANISM OF SENSITIZATION

The mechanism of sensitization depends on the type of allergy involved. The inhalants, as the name suggests, occur in the environment of the patient or in the atmosphere, creating sensitization through the respiratory tract. Pollens, ubiquitous and probably uncontrollable, fall into this category. Other inhalants, such as feathers and animal dander, are controllable. Allergens found in food cause symptoms upon ingestion, and these symptoms are alleviated by diet.

The presence of the allergic tendency, whether inherited or acquired, does not result in clinical allergy unless sensitization occurs by exposure to potent allergens. A large part of allergic treatment consists of elimination of offending allergens from the environment or the diet. This clinical procedure has given excellent results. Is it not wiser, then, to avoid exposure, thereby substituting prevention for the need of a cure?

The factor of food allergens is most important at the earliest period of life. Fortunately for this group, the dietary intake is most readily regulated at this time. Adequate infant feeding has two major requirements: normal growth must be maintained, and minimum vitamin and mineral requirements must be fulfilled. These two basic requirements can be met, while, at the same time, the exposure to potent allergens is lessened.

Food allergy has been recognized for many years, but it was not until 1916 that Schloss and Worthen<sup>2</sup> gave the first hint of its mechanics. In their classic paper they proved that foreign proteins are absorbed in unchanged form through the gastrointestinal tracts of normal infants and to a greater degree in those suffering from debility or any form of gastroenteritis. In 1920 Schloss<sup>3</sup> described the hyperacute type of sensitivity to food as evidenced by urticaria, asthma and symptoms of shock. The diagnosis of this condition is commonly made by the parents because of its obvious cause and effect relation. The symptoms are so distressing that the detection of the offending food is never a problem. Another type of sensitivity that brought on gastrointestinal disturbances with vomiting and diarrhea or skin manifestations such as eczema was described by the same author. In 1925 DuBois, Schloss and Anderson<sup>4</sup> reported that enteral absorption of antigenic protein by normal or marasmic infants led

not only to the appearance of a specific precipitin in the blood but also, in many cases, to cutaneous sensitivity. This fundamental work has been repeated by Wilson and Walzer<sup>5</sup> and other investigators.

Schloss and his co-workers<sup>6</sup> stated that the mechanism whereby the body is protected from the continued absorption of appreciable amounts of foreign protein was unknown. This statement still holds true today. They advanced three possible explanations, which continue to be of great interest by some means the gastrointestinal wall becomes impermeable to each newly introduced protein after it has been ingested for a certain length of time, an alteration in the digestive enzymes takes place so that they ultimately become capable of producing complete denaturation, and finally, even though foreign protein is absorbed as such, it may be neutralized by some hitherto unrecognized immune reactions. It has been observed by Rackemann<sup>7</sup> and others<sup>8</sup> that children frequently manifest the first symptoms of hypersensitivity to antigenic substances a few days or weeks after initial exposure. This interval coincides with the development of the antibodies as observed by Schloss and his co-workers<sup>6</sup>. In the average infant this immunologic process is passed over without incident. In the infant with the inherited tendency to hypersensitivity, Schloss and his associates<sup>6</sup> have reasoned that this mechanism may be altered so that the clinical manifestations of allergy result.

### BASIC FOODS IN INFANT FEEDING

The basic foods in infant feeding are milk, egg, wheat, orange juice and fish oil. These foods are added to the diet at varying ages, depending on the fashion of the moment and, to a lesser degree, on the school of thought to which the practicing pediatrician subscribes. Allergists<sup>9</sup> have found these five foods to be the most common sources of allergic manifestations in infants and young children. Laboratory workers have used the same allergens to prove the absorption of undigested protein through the gastrointestinal tract. Thus, there is the rare circumstance of five basic foods, ever-present in infant feeding, that are potent allergens and are readily absorbed unchanged through the mucous membrane of the gastrointestinal tract.

In summary, a large number of infants are potentially allergic by reason of heredity. Five basic food requirements of the infant diet are potent allergens, and these proteins are absorbed unchanged through the gastrointestinal tract. Is it not logical, then, to diminish the potency of these allergens by introducing them into the diet in a denatured form or to avoid them whenever possible?

Milk holds a unique position in the infant diet, unparalleled by any one food in adult life. Hill<sup>10</sup> pointed out that the infant takes enormous quantities of milk in proportion to his weight. He

The problem of pollen sensitivity, which is common in early life, may be raised at this point. The unequivocal answer to this question must be that nothing can be done to prevent such sensitization. It seems likely, however, that environmental or dietary factors are often operative first in destroying the allergic balance of the potentially allergic infant.

### DISCUSSION

This article offers no statistics supporting its proposed program. Any valid statistical study would require large numbers of patients observed over many years. Since the study of inheritance is so complicated, reports of individual cases successfully avoiding allergic manifestations can neither refute nor support the aim of the proposed regime for allergic prophylaxis.

The maintenance of allergic balance is considered very important in the potentially allergic person. Often a minor sensitization is believed to set off an extensive chain of symptoms. In infancy every precaution that may defer the upset of this balance should be taken.

A program such as that set forth is readily carried out. It calls for no major deviation from generally accepted practice in infant care. All that is necessary is a knowledge of the infant's inherited allergic tendencies, together with an awareness of the relative allergic potencies of each of the major foods and inhalants.

If prophylaxis fails in this group, a new awareness of the sources and onset of allergy will make detection of offending substances much simpler.

### SUMMARY

An attempt is made to define the potentially allergic infant and to review the current information about the mechanisms involved in the development of allergy. In the practice of allergy, many cases

are studied that require the removal of offending foods as well as other allergens. Their elimination is generally advised only after symptoms have developed. Clinical experience has shown the importance of five major food allergens. On the basis of the information provided by the literature and clinical knowledge, a program is outlined for the control of environment and of food intake that has as its aim the prevention of allergic symptoms in infants. This program is presented as an aid to those taking care of children and employs no radical deviation from the accepted procedures of pediatric care.

pital routine. This may lead to sensitization later. If allergic symptoms do appear on an evaporated-milk formula, it is safe to assume that milk casein is the offender and no type of animal milk will improve the condition. In these cases, which fortunately are rare, soy-bean milk should be substituted. Once evaporated milk has been instituted and no symptoms occur, it should be continued as the only type of milk given for the entire first year of life. At the termination of this period, absorption of undigested protein through the intestinal tract is less likely to occur.

An essential ingredient in every infant's formula is the added carbohydrate. Corn syrup in the form of Karo is commonly used for this purpose. Randolph<sup>17</sup> suggests that corn in all forms is a potent allergen. More work may be necessary to confirm this finding, but its probable allergenicity can be avoided with ease. Dexin, a product of Burroughs and Wellcome, does not contain corn sugar but has been found excellent in infant feeding. Such a simple substitution is worthy of trial.

Between the ages of one and four weeks it is essential to add vitamins A, D and C to the average infant's diet. In the group of potentially allergic children, this should be done by the use of ascorbic acid for vitamin C and provitol or any other synthetic for vitamins A and D. By these simple expedients one can avoid exposure to fish oil or natural orange juice. Here, too, avoidance should be continued at least until the infant has reached one year of age.

The proper age for the introduction of solid foods into the infant diet has long been a disputed point. In view of the ease with which undigested protein is assimilated through the gastrointestinal tract of the infant, caution should be exercised. Three or four months of age seems a proper time, albeit an arbitrary one.

As important as the age of introduction of solid food is the type of food selected for each increase in the infant diet. Since the infants under discussion are readily sensitized by any type, it is imperative to introduce one simple food at a time. For some years it has been the custom to start with prepared cereals such as pablum and cerevim. Unfortunately these cereals represent combinations of cereals that are not indicated by their trade names. Should sensitization occur, identification of the offending allergen becomes very difficult. Pablum, for example, contains farina, oat meal, wheat germ, yellow corn meal, powdered beef bone, powdered alfalfa leaf and powdered yeast. Cerevim contains whole-wheat meal, oatmeal, wheat germ, powdered skimmed cow's milk, yellow corn meal, dried brewer's yeast, barley and malt.

I prefer the introduction of cereals in the form of rice, the least antigenic of all the cereals. Wheat may be introduced, but in a pure form, such as

cream of wheat. Then, if allergic symptoms occur, identification of the offender is facilitated.

Egg may then be introduced as hard-boiled yolk. If no reaction takes place after two to four weeks of daily ingestion, one may safely assume that no sensitization has occurred, and proceed to add egg white in small quantities.

At about the age of six months, vegetables may be introduced. There is a growing tendency to use combinations of vegetables at the start. This procedure should be avoided. Single vegetables added at an interval of two to four weeks will simplify the identification of a sensitizing agent. After a sufficient number of vegetables have been tolerated, the infant is ready to be given vegetable soups, but in offering such mixtures, one must avoid the use of commercial soups that often contain "fillers" such as barley.

Beef juice may be introduced at about eight or nine months of age. If well tolerated in the allergic sense, one different well cooked meat may be added at each monthly change of diet.

Although in the potentially allergic infant, food is of prime importance in precipitating allergic manifestations, environmental factors cannot be exonerated. Fortunately, the environment of infants can be controlled. Care must be exercised from the moment the infant is brought home from the hospital and precautionary measures must be taken in the establishment of allergic cleanliness in the nursery. The infant's mattress should be covered with a dust-proof covering. Better yet is the use of the newer foam-rubber mattress. Feather pillows should be avoided. The new glass-fiber pillow is a good substitute. No feather puffs or comforters should be permitted in the room. Wall-to-wall carpeting with ozite padding is inadvisable in the nursery. Linoleum, which can be kept free of dust, is ideal. Washable glass curtains can be substituted for heavy draperies.

No insect sprays or pyrethrum compounds should be used in the nursery. There is no point in exposing potentially allergic infants to heavy doses of pyrethrum, which is closely related to ragweed pollen.

No wooly stuffed toys should be introduced for these children to play with. These toys are commonly stuffed with cotton lint or kapok, both of which are potent allergens.

The hygiene of an infant requires the frequent use of baby powder. It is a simple matter to provide a nonallergic dusting powder. Highly scented baby oil should also be avoided. Shampoo lotions as allergens are well recognized, and such lotions need not be employed. A simple castile soap will serve adequately.

Domestic-animal contacts in the home are one of the commonest sources of early sensitivity. If the introduction of dogs, cats, birds or rabbits into the homes of such infants is avoided, a great deal of difficulty in later life may be averted.

in which the tip of the tube actually perforated the small intestine. It appears that little can be done to prevent perforation except the discontinuance of the procedure as soon as possible.

When it is thought that the tube is no longer necessary it is good policy to stop suction a reasonable length of time before the actual withdrawal.<sup>1</sup> Leigh, Nelson and Swenson<sup>2</sup> believe that a tube should either reach a definite obstruction or proceed as far as the cecum in all cases before it is removed.

The following brief case report describes an unusual development encountered during the withdrawal of a Miller-Abbott tube.

Mrs. E. F. (B. I. H. 92980), a 72-year-old woman, was admitted to the hospital on February 28, 1947, after she had sustained an incomplete intertrochanteric fracture of the femur. Buck's extension apparatus was applied, and the patient did well until March 6, when she began to suffer from ileus. Nausea, vomiting and mild distention led to the use of a Miller-Abbott tube, which relieved her distress. On March 9 withdrawal of the tube was attempted, and during this maneuver the patient developed serious respiratory difficulty, and became moderately cyanotic. The tube seemed to be fixed when the markers indicated that about 120 cm. was still to be withdrawn. The pharynx was inspected, and three lengths of tubing could be seen lying against the posterior wall. One of the lengths was grasped and the knotted mass of tubing shown in Figure 1 was extracted from the nasopharynx.

### DISCUSSION

In this case the tube was used as a therapeutic measure primarily, intrinsic intestinal disease merely

being kept in mind. There was no reason strongly to suspect either mechanical obstruction or physiologic obstruction other than on the basis of a benign ileus. Because there was clinical evidence that the tip was past the pylorus (almost pure bile in the drain bottle soon after it was passed) and because almost immediately the tube was successful in relieving the patient's distress, no x-ray examination was carried out. The tube was passed on the assumption that it was in the small intestine.

Only in retrospect is the value of knowing everything possible about the tube demonstrated. The knot should certainly have been discovered had routine x-ray or fluoroscopic study been carried out. Because this complication is preventable and can be circumvented by anticipation when discovered this case is reported. A similar incident could occur with any of the modifications of the original Miller-Abbott tube.

## PRIMARY ATTACK OF VIVAX MALARIA OCCURRING TWENTY-SEVEN MONTHS AFTER INFECTION\*

WILLIAM S. JORDAN, JR., M.D.†

CLEVELAND, OHIO

TROPICAL diseases, particularly malaria, have assumed greatly increased diagnostic and therapeutic importance in this country with the return of servicemen from endemic areas.<sup>1-4</sup> Studies of the natural course of relapsing vivax malaria<sup>5, 6</sup> have led to the prediction that cases of this disease, acquired in the Southwest Pacific, would continue to appear for at least three years after the return of the last serviceman.<sup>4-7</sup> In addition, the use of quinacrine (atabrine) for the suppression of malaria has delayed the onset of the primary attack for months, whereas the normal intrinsic incubation period is eight to seventeen days.<sup>8</sup> Discontinuance of suppressive therapy in infected subjects is usually followed by symptoms within two to ten weeks, but occasionally the first clinical symptoms of malaria may be delayed for months.

Reviews of the Army and Navy experience have indicated that the longest interval thus far observed in such cases from last exposure to onset of the primary attack has been eighteen months.<sup>7, 9</sup>

This report records the occurrence of the first symptoms of vivax malaria in an ex-serviceman twenty-seven months after his return from an endemic area.

### CASE REPORT\*

A 28-year-old married salesman entered the hospital on December 6, 1947, complaining of chills and fever. Five days prior to admission, he had awakened with a mild, generalized headache, stiffness in his neck muscles and slight malaise. The headache and malaise increased during the day, and by evening he felt alternately chilly and feverish. On the following morning he felt better, but his symptoms returned that afternoon and his temperature reached 102.2°F. Three days before entry, he was given penicillin orally because of persistent symptoms and a temperature of 103.1°F. On the next afternoon, his headache became severe, and he experienced a shaking chill of 2 hours' duration during which his temperature rose to 104.9°F, and he became delirious. Drenching sweats followed, and

## AN UNUSUAL COMPLICATION OF MILLER-ABBOTT INTUBATION

## Report of a Case

LIEUTENANT JOSEPH E CARUOLO, M C, A U S

**I**NTUBATION of the small intestine has become an invaluable diagnostic and therapeutic measure, so fundamental that when indicated it is used routinely and not extraordinarily. Too often, however, a procedure seems to attract attention proportional only to its novelty. All are concerned with what an intestinal decompression tube is doing for the patient, but few are concerned with what is being done for the tube so long as it appears to be functioning.

There is much literature on intubation. It teaches that the procedure should be used with deliberation at all times. This report stresses care in its

fully before it is passed. It must be clean, deodorized, without leaks and, above all, patent. The Miller-Abbott balloon should have sufficient slack to prevent curling of the tip after it is inflated.<sup>1</sup> Whenever mercury is used the operator must be certain that it will not escape. A report, including 2 cases of mercury free within the gastrointestinal tract, shows that mercury is not absorbed and, therefore, not toxic. It is unreasonable, however, to elaborate devices designed to aid in the passage of the tube and at the same time to permit the escape of their essential element.<sup>4</sup>

Several measures that are sometimes indicated better prepare the patient. Small doses of morphine and atropine about half an hour before intubation have two functions. Apprehension is often reduced to a desirable minimum. It has been suggested moreover that fear and excitement not only deprive the patient of co-operation but also tend to produce hypertonicity of gastric cardia and the pylorus, two most important obstacles a tube must overcome. For patients with small nasal passages and for those who are hypersensitive, a solution of ephedrine and pontocaine will provide extra room and will lessen sensation.<sup>4</sup> None but experienced personnel should attempt to pass a tube of any sort, or more precisely, no one who does not appreciate his limitations should be allowed to pass a tube. Recently a well meaning attendant decided to pass a tube that the patient had dislodged. She admitted that there was considerable coughing and gagging but could not believe that this caused the patient to lose his voice for two months. An ear, nose and throat specialist described the vocal cords as edematous without any other signs of trauma. It is quite conceivable that at the time it occurred the incident could have led to serious respiratory embarrassment.<sup>5</sup>

Once in the stomach the tube should be passed *pari passu* with its progress through the pylorus, never faster, for curled tubing in the stomach serves no purpose except that of creating the complication reported below. It is agreed that x-ray examination and fluoroscopy are the only infallible indicators of the position of the tube. The thick mucinous secretions of the stomach, which tend to bog the advance of the tube, can partially be neutralized by allowing clear fluids by mouth temporarily. Electrolytes thus washed away must be replaced quantitatively. The literature contains innumerable discussions of this relation.<sup>6</sup> Frequent irrigations of the tube are always indicated.

A most serious complication has been reported recently by Berger and Achs,<sup>7</sup> who describe a case

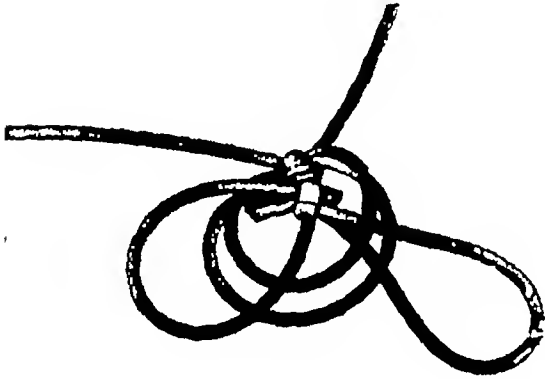

FIGURE 1 *Knotted Mass of Tubing Extracted from the Nasopharynx*

use routinely, especially when it is decided that the tube be removed. It is not intended fully to discuss the subject.

Complications arising from ill advised use of intubation are obviously the most serious. In strangulation, for example, when the tube is considered more than an adjunct, disaster is inevitable. Here, intubation can serve only to mask the gravity of the situation.<sup>1</sup> Temporizing in cases of excellent functioning of the tube without clinical improvement of the patient is treating the tube and not the patient. Conversely, a tube that refuses to function in a patient who is definitely getting better carries no weight for intervention.<sup>2</sup> A further contraindication is the treatment of obstruction of the large intestine with distention of a segment of bowel defined by the point of obstruction and the ileocecal valve.<sup>3</sup> While generalized distention is abating a closed segment is maintained under localized distention because of the unilateral flow permitted by the valve.

The preparation of the tube for the patient is a primary consideration. It must be inspected care-

in which the tip of the tube actually perforated the small intestine. It appears that little can be done to prevent perforation except the discontinuance of the procedure as soon as possible.

When it is thought that the tube is no longer necessary it is good policy to stop suction a reasonable length of time before the actual withdrawal.<sup>1</sup> Leigh, Nelson and Swenson<sup>2</sup> believe that a tube should either reach a definite obstruction or proceed as far as the cecum in all cases before it is removed.

The following brief case report describes an unusual development encountered during the withdrawal of a Miller-Abbott tube.

Mrs. E. F. (B. I. H. 92980), a 72-year-old woman, was admitted to the hospital on February 28, 1947, after she had sustained an incomplete intertrochanteric fracture of the femur. Buck's extension apparatus was applied, and the patient did well until March 6, when she began to suffer from ileus. Nausea, vomiting and mild distention led to the use of a Miller-Abbott tube, which relieved her distress. On March 9 withdrawal of the tube was attempted, and during this maneuver the patient developed serious respiratory difficulty, and became moderately cyanotic. The tube seemed to be fixed when the markers indicated that about 120 cm. was still to be withdrawn. The pharynx was inspected, and three lengths of tubing could be seen lying against the posterior wall. One of the lengths was grasped and the knotted mass of tubing shown in Figure 1 was extracted from the nasopharynx.

### DISCUSSION

In this case the tube was used as a therapeutic measure primarily, intrinsic intestinal disease merely

being kept in mind. There was no reason strongly to suspect either mechanical obstruction or physiologic obstruction other than on the basis of a benign ileus. Because there was clinical evidence that the tip was past the pylorus (almost pure bile in the drain bottle soon after it was passed) and because almost immediately the tube was successful in relieving the patient's distress, no x-ray examination was carried out. The tube was passed on the assumption that it was in the small intestine.

Only in retrospect is the value of knowing everything possible about the tube demonstrated. The knot should certainly have been discovered had routine x-ray or fluoroscopic study been carried out. Because this complication is preventable and can be circumvented by anticipation when discovered this case is reported. A similar incident could occur with any of the modifications of the original Miller-Abbott tube.

†Teaching fellow, Departments of Preventive Medicine and Medicine, School of Medicine, Western Reserve University and the University Hospitals.

\*This case is reported through the kindness of Dr. Harley A. Williams.

by the morning of the day prior to admission his temperature was normal and he was essentially asymptomatic. Another severe chill accompanied by prostration and delirium occurred the next day and he was hospitalized.

The past history included 2 years of military service, 1943-1945, in New Guinea and the Philippines. During this time the patient had had no illness requiring hospitalization and no symptoms suggestive of malaria. He took suppressive quinacrine daily until his return to the United States in September, 1945. He remained in Northern Ohio and had suffered only minor respiratory illnesses since that date.

Physical examination showed a well developed and well nourished, acutely ill man, who was rational, but weak and drowsy. Slight conjunctival injection and a firm, nontender spleen palpable 3 cm below the costal margin were the only abnormal physical findings.

The temperature was 103.1°F by rectum, the pulse 106, and the respirations 24. The blood pressure was 110/66.

Examination of the blood showed a red-cell count of 4,800,000, with a hemoglobin of 12 gm per 100 cc, and a white-cell count of 8800, with a normal differential. Routine urinalyses showed no abnormalities. An aerobic blood culture was sterile. Cultures of the throat and sputum failed to detect pneumococci, beta-hemolytic streptococci or staphylococci. An anteroposterior roentgenogram of the chest was interpreted as showing accentuation of hilar markings but no definite infiltration. Examination of thin blood smears at the time of admission showed no malarial parasites. A thick film was not made until the next morning, when the temperature was normal. This and subsequent smears were negative.

Without therapy, the patient's temperature fell to normal within 12 hours and he remained afebrile and asymptomatic until discharge on the 5th hospital day. Despite the failure to demonstrate the parasites, his clinical picture was very suggestive of malaria. Moreover, it was learned that he had received 1.0 gm (15 gr) of quinine on the morning of admission. The diagnosis was confirmed when he was readmitted 6 days later because of recurrent chills and fever. His physical findings were unchanged, but many colonies of *Plasmodium vivax* were demonstrable in routine blood smears. Quinacrine therapy induced a prompt remission, and he was discharged free from symptoms.

### DISCUSSION

This case, with the long latent period, raises the question of a more recent exposure and illustrates the diagnostic difficulties that may be encountered in a patient with malaria. Since rare cases of malaria apparently acquired in the Cleveland area have been observed,<sup>10</sup> it is possible that this patient's infection was contracted locally. Against this possibility is the time of year, December, the known previous exposure in a highly endemic area and the size of the spleen. Such splenomegaly suggests, according to Boyd,<sup>1</sup> reactivation of a latent infection.

The onset of fever, which was at first sustained but later remittent in the tertian pattern, resembles that seen in the first attack of natural malaria<sup>8</sup> or that observed in many delayed primary attacks.<sup>6-9</sup>

Early administration of only a small amount of quinine was sufficient to halt the paroxysms temporarily, confuse the clinical picture and delay diagnosis. Use of a sulfonamide might have produced the same result.<sup>11</sup>

Although the usual incubation period of unmodified malaria is approximately eight to seventeen days, longer natural latent periods have frequently been observed. Shute<sup>12</sup> recently reviewed the problem of latency and long-term relapses in malaria and reported an average latent period

of two hundred and eighty-two days in 9 cases under natural conditions. He pointed out cases, particularly those reported from the Netherlands, of attacks in early spring from infection acquired the previous summer or autumn. Students of the disease are familiar with the occurrence of the first malarial attack upon arrival in a cooler climate, and protracted latent periods of ten months are mentioned.<sup>13</sup> No account was found of a primary attack occurring as long as twenty-seven months after the last exposure.

It seems reasonable to attribute this alteration in the incubation period of the disease to quinacrine. Wartime experience showed that the mechanism of quinacrine protection in vivax malaria is not destruction of the infective organism but reduction of parasitemia to a level insufficient for the production of clinical symptoms.<sup>4</sup> Delayed primary attacks indicate prolonged survival of the postulated fixed-tissue or exoerythrocytic stage of the parasite, or a degree of immunity that, until altered, is able to suppress the parasitemia to subclinical levels. The present concept that malarial immunity is dependent on the occurrence of frequent relapses<sup>6</sup> tends to eliminate this factor in the case reported above.

Baker and Platt<sup>14</sup> reported a study of troops heavily infected with malaria on Guadalcanal and subsequently maintained on quinacrine suppression for eighteen months after their transfer to non-malarious areas. A greatly reduced relapse rate was noted during a three-month period of observation following withdrawal of quinacrine. Subject to the limitations of this period of observation, the authors concluded that "not only is the high malaria rate in heavily seeded troops temporarily controlled by atabrine suppressive medication but a highly significant amount of clinical vivax malaria is permanently abolished." It is difficult, as they suggest, to know whether to ascribe such apparent cures to the medication or merely to the passage of time with the development of immunity. The patient in the case reported above did not develop clinical malaria until more than four years after his first possible exposure and more than two years after his last exposure. Two years of suppressive quinacrine therapy during exposure did not prevent the eventual occurrence of overt disease.

Noe, Greene and Cheney<sup>6</sup> observed that patients, previously on suppressive quinacrine therapy, who have their first attack of malaria in this country show a tendency to run the complete two-year to three-year relapsing course of the disease. Should this patient show a similar tendency, and particularly if he is treated only with quinacrine, he might well suffer a malarial relapse as long as four or five years after his last exposure in the Southwest Pacific. This implies that physicians must continue to consider the possibility of malaria in febrile illnesses in veterans. The future experience of the

armed forces and the Veterans Administration will be of help in clarifying this problem, just as use of the new antimalarial drugs<sup>15, 16</sup> offers hope of its eventual solution

### SUMMARY

A primary attack of vivax malaria occurring in an ex-serviceman twenty-seven months after his last exposure in an endemic area is reported

Such prolonged latent periods have not been reported in natural malaria. Primary attacks occurring eighteen months after discontinuance of quinacrine suppression have been observed, and the effect of this drug is suggested as a possible explanation for the delayed attack in this patient. If this, or similar cases, show a tendency to further relapses, it would indicate that a small number of malaria relapses may continue to occur for four to five years after the return of the last serviceman from endemic areas in the Southwest Pacific

## MEDICAL PROGRESS

### PROCTOLOGY

E PARKER HAYDEN, M D \*

BOSTON

IN a comprehensive bibliography prepared for the 1947 meeting of the American Proctologic Society numerous articles on nonmalignant and malignant lesions of the colon and rectum, published during 1946, were carefully listed and indexed, and some of them abstracted in greater or less detail. With perhaps an equal number in the literature of 1947, it is apparent that a complete review of them is a task too extensive for inclusion in this rather short article. Spectacular advances in this field are the exception, — not the rule, — and yet articles of value and interest, contributed both by those who limit their work to proctology and by those who do not, have appeared from time to time.

The American Proctologic Society, organized in 1899 and holding yearly meetings since that time, has always published its papers in a series of bound volumes entitled *Transactions of the American Proctologic Society*, until this year. The February, 1948, issue of the *American Journal of Surgery* was devoted exclusively to publication of the papers read at the 1947 meeting of the society.

\*Associate visiting surgeon, Massachusetts General Hospital

At this meeting, a paper by Courtney,<sup>1</sup> was given the Hermance award as being the best original paper presented on that occasion. Courtney reported the results of a study carried out in the anatomic laboratories of the Graduate School of the University of Pennsylvania under supervision of Professor Batson of the Anatomy Department, in an effort further to clarify the classification and mode of extension of perirectal abscesses. Eight cadavers were dissected in detail, and 40 cadavers were inspected while being dissected by others, both from above and below, and with the aid of sagittal, parasagittal and coronal sections.

Heretofore there have been described, and accepted as accurate, three deep spaces, — the retrorectal and the right and left pelvirectal spaces, — abscesses of which are recognized.

As a result of this study Courtney has identified a fourth deep space, to which he has given the name "posterior levator space." This space is formed by a division, close to the rectum, of the levator muscle attachment into a superior and inferior layer which produces a V-shaped flare with attachments at

different levels to the longitudinal muscle fibers of the rectum, thus creating a space, bounded by the longitudinal muscle of the rectum medially, by the superior and inferior muscle bundles of the levator above and below, and extending around the posterior surface of the rectum from side to side, decreasing in size and depth as the pubis is approached, and with its greatest size near the posterior midline.

Infection of this space arises by upward extension from one of the posterior crypts, and is characterized by formation of a deep abscess, not palpable externally but felt as a rounded swelling on intra-rectal palpation in the posterior midline.

Courtney advises incision in the midline posterior to the anus, spreading the fibers of the sphincter as they converge toward the coccyx. If the abscess has spread laterally a counterincision can be made lateral to the sphincter and as far forward as necessary.

#### PARASYMPATHETIC SUPPLY OF THE DISTAL COLON

On the basis of a dissection of 9 infant and 9 adult bodies, Lannon and Weller<sup>2</sup> found variations in parasympathetic distribution in practically every body, and in the two sides of any one body. On the left,

sympathetic fibers usually arise from the anterior aspect of the second and third sacral nerves within 1 cm. of their exit from the anterior sacral foramina. Well defined fibers pass anteriorly as the nervi erigentes, and from three to six moderately thick strands pass medially, upward and anteriorly, to the distal colon. The nerves are creamy white, and a tiny red blood vessel can be seen on the surface of the nerve—an identifying characteristic. Difficulty was encountered in tracing the fibers through the dense pelvic fascia, but it was possible to identify them in some of the dissections as giving off some fibers to the rectum just after piercing the fascia, the remainder passing down with the superior hemorrhoidal artery.

There was also found to be a connection of some fibers on the left with the inferior hypogastric plexus. At the level of the promontory the fibers leave the artery and pass across the left common iliac artery and upward into the mesentery of the bowel, where some fibers could be traced to the bowel itself as high as the midportion of the descending colon. They do not enter the bowel with the vessels, but independently.

On the right side the plan is similar in general except that the nerves tend to lie at a distance from the superior hemorrhoidal artery and in closer association with the inferior hypogastric plexus.

The authors believe that they have demonstrated several points of clinical interest—that in resections of the rectum and pelvic colon the parasympathetic vessels are bound to be destroyed—a fact that has always been considered to be true. On the other hand a periarterial stripping of the inferior mesen-

teric artery and presacral neurectomy should not interfere with the parasympathetic supply to any part of the colon, but in a high colonic resection the part of the colon lying above the point of resection and below the distal point of vagal parasympathetic supply will be deprived of its parasympathetic supply.

#### ANORECTAL AND URINARY DYSFUNCTION

McCrae<sup>3</sup> discusses the intimate relation between anorectal and urinary dysfunctions on the basis of the common blood supply and innervation of the two areas. The bladder and the anorectum both originate from the fetal cloaca in their embryologic stage. Each is supplied with blood from the hypogastric artery by its various branches, though the rectum also receives some of its blood by way of the superior hemorrhoidal artery from the inferior mesenteric.

Each organ is likewise innervated by the somatic, sympathetic and parasympathetic systems. Somatic supply is by way of the pudendal nerve from the second, third and fourth sacral vessels. It is through this nerve that the voluntary impulses of urination are carried. Another branch of the pudendal, the inferior hemorrhoidal nerve, supplies the anal region. The pudendal nerve is both motor and sensory and on this fact is best explained the retention of urine following hemorrhoidectomy and other anal procedures, owing to a reflex contraction of the external vesical sphincter following trauma to the perineal branch of the pudendal nerve.

#### PERFORATIONS OF THE COLON

Andresen<sup>4</sup> has gathered some interesting facts regarding perforations of the bowel during proctoscopy. His figures are based on 215 replies to questionnaires sent to 340 members of the American Gastro-Enterological Association and the American Proctologic Society. From 34 of these replies he received reports of 46 cases of perforation, which he has analyzed.

Onset with sudden pain occurred in only 2 patients (55 per cent).

Diagnosis was made by direct observation through the proctoscope in 25 cases (54 per cent).

In the 46 cases 21 patients had no other disease of sigmoid or rectum. There were 13 carcinomas, 5 others with diverticula in the sigmoid, 3 with ulcerative colitis, 2 with polyps, 1 with lymphopathia venereum, and 1 with hemorrhoids only. Nineteen patients, or 41 per cent, died, including the 3 patients who were not operated on.

Immediate operation showed a mortality of 8 per cent, and when operation was delayed one to six hours the mortality was 32 per cent, from six to twelve hours, 50 per cent, and over twelve hours 75 per cent.

The best results were obtained in 8 cases in which colostomy was performed, 2 with suture and 6

without suture of the perforation Only 1 of the 8 patients died In 23 cases in which the perforation was closed, but colostomy not done, there were 6 deaths Of 22 patients not operated upon, in the two series of cases, there were 13 deaths (59 per cent) Nine recovered

The over-all mortality in the 94 cases was 47 per cent Andresen emphasizes the importance of passing a proctoscope only under direct vision, and discontinuing the attempt if poor preparation, bleeding, spasm and so forth make it impossible to obtain a good view

I should like to urge, in addition to these precautions, that proctoscopic examinations not be made on patients under anesthesia, and in lithotomy position, if they can be avoided More information can be obtained, and with less risk, if proctoscopy is performed with the patient in the inverted, or in the knee-shoulder position, prior to anesthesia

Davis<sup>5</sup> reports 3 cases in which an enema tube, inserted through a colostomy stoma, perforated the sigmoid and permitted the enema fluid to enter the peritoneal cavity In 1 case immediate pain brought the patient to operation within 6 hours, and in the second case after three days, with signs of peritonitis, whereas the third patient was operated upon after three weeks with drainage of an abscess All recovered

This is an unusual occurrence though it has also happened in 2 of my patients who were taking their own enemas In 1, who had had for some time a colostomy for lymphopathia venerea with extensive rectal involvement, the perforation produced sudden pain with ensuing tenderness at one side of the stoma, but no fluid had been introduced and operation was never necessary, the small cavity, demonstrated by barium enema a little later, eventually obliterating itself My second patient came into the hospital with fever, distention and cramps, suggesting small-bowel obstruction After some decompression had been obtained with a Miller-Abbott tube, pus could be seen coming from the colostomy in small amount, the abscess having drained itself into the bowel In this case a colostomy was constructed at a higher point in the colon

#### PILONIDAL CYST AND SINUSES

Pilonidal-sinus problems seem to fall within the scope of this review by virtue of the proximity of the lesions to the anus and the natural gravitation of many of these patients to the offices and clinics of surgeons doing proctologic work Throughout the war, efforts were directed toward developing improved methods of reducing the healing period following operation, mostly by the use of primary closure in one form or another Many ways of accomplishing this have been described, and series of cases published, with more or less follow-up data, since Lahey described his method of sliding a flap of

skin, fat and fascia to the midline to fill in this poorly healing area

Pope<sup>6</sup> has reported a considerable experience at the Chelsea Naval Hospital with an operation that he devised, the principal feature of which is the sliding of a single mobilized section of gluteus muscle across the midline to obliterate the defect following excision of cyst and sinuses In 92 cases out of a series of 130, this operation was used, whereas 38 others were closed by primary suture without use of the sliding muscle graft Follow-up data were reserved for a subsequent article, but the results, so far as could be observed during the extended hospitalization often given to Army and Navy personnel, were very good

Success in achieving primary healing in pilonidal cyst excisions depends upon bacteriologic cleanliness of the lesion at time of operation, careful hemostasis and tissue handling, obliteration of dead space in the suturing process, and careful post-operative treatment, including chemotherapy

It is obvious, therefore, that good results will depend upon proper selection of patients, the use of a procedure best suited to the individual case, and upon the ability of the individual surgeon to carry through on the technical procedure and aftercare The open method still remains the most certain to produce a permanent healing

#### FISTULA

The old idea that most anal fistulas are tuberculous is once again refuted by a study that Jackman and Buie<sup>7</sup> carried out in 600 patients with anal fistula Of these only 11.5 per cent showed evidence of tuberculosis anywhere in the body, and in only 7 or 8 per cent was the fistula itself proved to be tuberculous There was no case of tuberculous fistula in a person who did not have tuberculosis elsewhere in the body These authors consider the guinea-pig inoculation with material from the fistula to be the best test of the nature of the fistula, though they admit that contamination of the area could occur from higher up in cases in which the histology of the fistula is negative for tuberculosis

Skir<sup>8</sup> has studied various reports in the literature, totaling 50 cases, in which carcinoma was considered to have developed from a previously existing fistula From this group he has selected 14 in which the fistula was known to have been present for at least ten years prior to the diagnosis of cancer, thereby strengthening the likelihood that the cancer really did supervene on the fistula To this group of 14 he adds 3 from the Brooklyn Hospital These 3 patients were elderly people, 2 of them Negroes, all with long histories of fistula — ten, thirty and fifty-five years of intermittent discharging sinus — and all presenting a similar picture that of a fungating, ulcerating tumor protruding from the fistulous buttock, through the skin of which it had ulcerated The pathological reports were

different levels to the longitudinal muscle fibers of the rectum, thus creating a space, bounded by the longitudinal muscle of the rectum medially, by the superior and inferior muscle bundles of the levator above and below, and extending around the posterior surface of the rectum from side to side, decreasing in size and depth as the pubis is approached, and with its greatest size near the posterior midline

Infection of this space arises by upward extension from one of the posterior crypts, and is characterized by formation of a deep abscess, not palpable externally but felt as a rounded swelling on intra-rectal palpation in the posterior midline

Courtney advises incision in the midline posterior to the anus, spreading the fibers of the sphincter as they converge toward the coccyx. If the abscess has spread laterally a counterincision can be made lateral to the sphincter and as far forward as necessary

#### PARASYMPATHETIC SUPPLY OF THE DISTAL COLON

On the basis of a dissection of 9 infant and 9 adult bodies, Lannon and Weller<sup>2</sup> found variations in parasympathetic distribution in practically every body, and in the two sides of any one body. On the left, the pelvic autonomic fibers usually arise from the anterior aspect of the second and third sacral nerves within 1 cm. of their exit from the anterior sacral foramina. Well defined fibers pass anteriorly as the *nervi erigentes*, and from three to six moderately thick strands pass medially, upward and anteriorly, to the distal colon. The nerves are creamy white, and a tiny red blood vessel can be seen on the surface of the nerve—an identifying characteristic. Difficulty was encountered in tracing the fibers through the dense pelvic fascia, but it was possible to identify them in some of the dissections as giving off some fibers to the rectum just after piercing the fascia, the remainder passing down with the superior hemorrhoidal artery.

There was also found to be a connection of some fibers on the left with the inferior hypogastric plexus. At the level of the promontory the fibers leave the artery and pass across the left common iliac artery and upward into the mesentery of the bowel, where some fibers could be traced to the bowel itself as high as the midportion of the descending colon. They do not enter the bowel with the vessels, but independently.

On the right side the plan is similar in general except that the nerves tend to lie at a distance from the superior hemorrhoidal artery and in closer association with the inferior hypogastric plexus.

The authors believe that they have demonstrated several points of clinical interest—that in resections of the rectum and pelvic colon the parasympathetic vessels are bound to be destroyed—a fact that has always been considered to be true. On the other hand a periarterial stripping of the inferior mesen-

teric artery and presacral neurectomy should not interfere with the parasympathetic supply to any part of the colon, but in a high colonic resection the part of the colon lying above the point of resection and below the distal point of vagal parasympathetic supply will be deprived of its parasympathetic supply.

#### ANORECTAL AND URINARY DYSFUNCTION

McCrae<sup>3</sup> discusses the intimate relation between anorectal and urinary dysfunctions on the basis of the common blood supply and innervation of the two areas. The bladder and the anorectum both originate from the fetal cloaca in their embryologic stage. Each is supplied with blood from the hypogastric artery by its various branches, though the rectum also receives some of its blood by way of the superior hemorrhoidal artery from the inferior mesenteric.

Each organ is likewise innervated by the somatic, sympathetic and parasympathetic systems. Somatic supply is by way of the pudendal nerve from the second, third and fourth sacral vessels. It is through this nerve that the voluntary impulses of urination are carried. Another branch of the pudendal, the inferior hemorrhoidal nerve, supplies the anal region. The pudendal nerve is both motor and sensory and on this fact is best explained the retention of urine following hemorrhoidectomy and other anal procedures, owing to a reflex contraction of the external vesical sphincter following trauma to the perineal branch of the pudendal nerve.

#### PERFORATIONS OF THE COLON

Andresen<sup>4</sup> has gathered some interesting facts regarding perforations of the bowel during proctoscopy. His figures are based on 215 replies to questionnaires sent to 340 members of the American Gastro-Enterological Association and the American Proctologic Society. From 34 of these replies he received reports of 46 cases of perforation, which he has analyzed.

Onset with sudden pain occurred in only 26 patients (55 per cent).

Diagnosis was made by direct observation through the proctoscope in 25 cases (54 per cent).

In the 46 cases 21 patients had no other disease of sigmoid or rectum. There were 13 carcinomas, 5 others with diverticula in the sigmoid, 3 with ulcerative colitis, 2 with polyps, 1 with lymphopathia venereum, and 1 with hemorrhoids only. Nineteen patients, or 41 per cent, died, including the 3 patients who were not operated on.

Immediate operation showed a mortality of 8 per cent, and when operation was delayed one to six hours the mortality was 32 per cent, from six to twelve hours, 50 per cent, and over twelve hours 75 per cent.

The best results were obtained in 8 cases in which colostomy was performed, 2 with suture and 6

without suture of the perforation. Only 1 of the 8 patients died. In 23 cases in which the perforation was closed, but colostomy not done, there were 6 deaths. Of 22 patients not operated upon, in the two series of cases, there were 13 deaths (59 per cent). Nine recovered.

The over-all mortality in the 94 cases was 47 per cent. Andresen emphasizes the importance of passing a proctoscope only under direct vision, and discontinuing the attempt if poor preparation, bleeding, spasm and so forth make it impossible to obtain a good view.

I should like to urge, in addition to these precautions, that proctoscopic examinations not be made on patients under anesthesia, and in lithotomy position, if they can be avoided. More information can be obtained, and with less risk, if proctoscopy is performed with the patient in the inverted, or in the knee-shoulder position, prior to anesthesia.

Davis<sup>5</sup> reports 3 cases in which an enema tube, inserted through a colostomy stoma, perforated the sigmoid and permitted the enema fluid to enter the peritoneal cavity. In 1 case immediate pain brought the patient to operation within 6 hours, and in the second case after three days, with signs of peritonitis, whereas the third patient was operated upon after three weeks with drainage of an abscess. All recovered.

This is an unusual occurrence though it has also happened in 2 of my patients who were taking their own enemas. In 1, who had had for some time a colostomy for lymphopathia venerea with extensive rectal involvement, the perforation produced sudden pain with ensuing tenderness at one side of the stoma, but no fluid had been introduced and operation was never necessary; the small cavity, demonstrated by barium enema a little later, eventually obliterating itself. My second patient came into the hospital with fever, distention and cramps, suggesting small-bowel obstruction. After some decompression had been obtained with a Miller-Abbott tube, pus could be seen coming from the colostomy in small amount, the abscess having drained itself into the bowel. In this case a colostomy was constructed at a higher point in the colon.

#### PILONIDAL CYST AND SINUSES

Pilonidal-sinus problems seem to fall within the scope of this review by virtue of the proximity of the lesions to the anus and the natural gravitation of many of these patients to the offices and clinics of surgeons doing proctologic work. Throughout the war, efforts were directed toward developing improved methods of reducing the healing period following operation, mostly by the use of primary closure in one form or another. Many ways of accomplishing this have been described, and series of cases published, with more or less follow-up data, since Lahey described his method of sliding a flap of

skin, fat and fascia to the midline to fill in this poorly healing area.

In 92 cases out of a series of 130, this operation was used, whereas 38 others were closed by primary suture without use of the sliding muscle graft. Follow-up data were reserved for a subsequent article, but the results, so far as could be observed during the extended hospitalization often given to Army and Navy personnel, were very good.

Success in achieving primary healing in pilonidal cyst excisions depends upon bacteriologic cleanliness of the lesion at time of operation, careful hemostasis and tissue handling, obliteration of dead space in the suturing process, and careful post-operative treatment, including chemotherapy.

It is obvious, therefore, that good results will depend upon proper selection of patients, the use of a procedure best suited to the individual case, and upon the ability of the individual surgeon to carry through on the technical procedure and aftercare. The open method still remains the most certain to produce a permanent healing.

#### FISTULA

The old idea that most anal fistulas are tuberculous is once again refuted by a study that Jackman and Buie<sup>7</sup> carried out in 600 patients with anal fistula. Of these only 11.5 per cent showed evidence of tuberculosis anywhere in the body and in only 7 or 8 per cent was the fistula itself proved to be tuberculous. There was no case of tuberculous fistula in a person who did not have tuberculosis elsewhere in the body. These authors consider the guinea-pig inoculation with material from the fistula to be the best test of the nature of the fistula, though they admit that contamination of the area could occur from higher up in cases in which the histology of the fistula is negative for tuberculosis.

Skir<sup>8</sup> has studied various reports in the literature, totaling 50 cases, in which carcinoma was considered to have developed from a previously existing fistula. From this group he has selected 14 in which the fistula was known to have been present for at least ten years prior to the diagnosis of cancer, thereby strengthening the likelihood that the cancer really did supervene on the fistula. To this group of 14 he adds 3 from the Brooklyn Hospital. These 3 patients were elderly people, 2 of them Negroes, all with long histories of fistula — ten, thirty and fifty-five years of intermittent discharging sinus — and all presenting a similar picture that of a fungating, ulcerating tumor protruding from the fistulous buttock, through the skin of which it had ulcerated. The pathological reports were

different levels to the longitudinal muscle fibers of the rectum, thus creating a space, bounded by the longitudinal muscle of the rectum medially, by the superior and inferior muscle bundles of the levator above and below, and extending around the posterior surface of the rectum from side to side, decreasing in size and depth as the pubis is approached, and with its greatest size near the posterior midline.

Infection of this space arises by upward extension from one of the posterior crypts, and is characterized by formation of a deep abscess, not palpable externally but felt as a rounded swelling on intra-rectal palpation in the posterior midline.

Courtney advises incision in the midline posterior to the anus, spreading the fibers of the sphincter as they converge toward the coccyx. If the abscess has spread laterally a counterincision can be made lateral to the sphincter and as far forward as necessary.

#### PARASYMPATHETIC SUPPLY OF THE DISTAL COLON

On the basis of a dissection of 9 infant and 9 adult bodies, Lannon and Weller<sup>2</sup> found variations in parasympathetic distribution in practically every body, and in the two sides of any one body. On the left, the pelvic autonomic fibers usually arise from the anterior aspect of the second and third sacral nerves within 1 cm. of their exit from the anterior sacral foramina. Well defined fibers pass anteriorly as the nervi erigentes, and from three to six moderately thick strands pass medially, upward and anteriorly, to the distal colon. The nerves are creamy white, and a tiny red blood vessel can be seen on the surface of the nerve—an identifying characteristic. Difficulty was encountered in tracing the fibers through the dense pelvic fascia, but it was possible to identify them in some of the dissections as giving off some fibers to the rectum just after piercing the fascia, the remainder passing down with the superior hemorrhoidal artery.

There was also found to be a connection of some fibers on the left with the inferior hypogastric plexus. At the level of the promontory the fibers leave the artery and pass across the left common iliac artery and upward into the mesentery of the bowel, where some fibers could be traced to the bowel itself as high as the midportion of the descending colon. They do not enter the bowel with the vessels, but independently.

On the right side the plan is similar in general except that the nerves tend to lie at a distance from the superior hemorrhoidal artery and in closer association with the inferior hypogastric plexus.

The authors believe that they have demonstrated several points of clinical interest—that in resections of the rectum and pelvic colon the parasympathetic vessels are bound to be destroyed—a fact that has always been considered to be true. On the other hand a periarterial stripping of the inferior mesen-

teric artery and presacral neurectomy should not interfere with the parasympathetic supply to any part of the colon, but in a high colonic resection the part of the colon lying above the point of resection and below the distal point of vagal parasympathetic supply will be deprived of its parasympathetic supply.

#### ANORECTAL AND URINARY DYSFUNCTION

McCrae<sup>3</sup> discusses the intimate relation between anorectal and urinary dysfunctions on the basis of the common blood supply and innervation of the two areas. The bladder and the anorectum both originate from the fetal cloaca in their embryologic stage. Each is supplied with blood from the hypogastric artery by its various branches, though the rectum also receives some of its blood by way of the superior hemorrhoidal artery from the inferior mesenteric.

Each organ is likewise innervated by the somatic, sympathetic and parasympathetic systems. Somatic supply is by way of the pudendal nerve from the second, third and fourth sacral vessels. It is through this nerve that the voluntary impulses of urination are carried. Another branch of the pudendal, the inferior hemorrhoidal nerve, supplies the anal region. The pudendal nerve is both motor and sensory and on this fact is best explained the retention of urine following hemorrhoidectomy and other anal procedures, owing to a reflex contraction of the external vesical sphincter following trauma to the perineal branch of the pudendal nerve.

#### PERFORATIONS OF THE COLON

Andresen<sup>4</sup> has gathered some interesting facts regarding perforations of the bowel during proctoscopy. His figures are based on 215 replies to questionnaires sent to 340 members of the American Gastro-Enterological Association and the American Proctologic Society. From 34 of these replies he received reports of 46 cases of perforation, which he has analyzed.

Onset with sudden pain occurred in only 26 patients (55 per cent).

Diagnosis was made by direct observation through the proctoscope in 25 cases (54 per cent).

In the 46 cases 21 patients had no other disease of sigmoid or rectum. There were 13 carcinomas, 5 others with diverticula in the sigmoid, 3 with ulcerative colitis, 2 with polyps, 1 with lymphopathia venereum, and 1 with hemorrhoids only. Nineteen patients, or 41 per cent, died, including the 3 patients who were not operated on.

Immediate operation showed a mortality of 8 per cent, and when operation was delayed one to six hours the mortality was 32 per cent, from six to twelve hours, 50 per cent, and over twelve hours 75 per cent.

The best results were obtained in 8 cases in which colostomy was performed, 2 with suture and 6

are then undercut. Complete closure of the wounds occurs in about a month, and Kallet advises digital dilations of the anus periodically.

The difference between this procedure and the old undercutting operation, as advocated by Ball, lies in the excision of skin that characterizes the former, whereas in the latter little or no skin is sacrificed.

Discussion of this paper brought forth varying reactions, including emphasis on the value of subcutaneous alcohol injection as a substitute for too radical excision of skin and mention of the value of including some degree of anal-canal surgery — removal of papillae and crypts, and partial incision of the anal ring to relieve tightness — in association with the external work. Kallet, in closing the discussion, strongly urged that no intra-anal cutting be done and emphasized that in most of these cases the anal canal is found to be quite normal. In the last statement I agree with him.

#### HEMOSTATIC AGENTS

Rosser<sup>12</sup> reported, as an experimental study in 141 anorectal operations, the use of gelatin sponge (gel foam), oxidized cotton or oxidized gauze as a packing in the wounds at time of operation. Fibrin foam was not tried because of its origin in human blood, which might make it less available. Rosser cites the experimental work of several authors indicating that gelatin sponge is nonirritating and gradually absorbable. He used it in 43 anorectal wounds and found that it usually disappeared in forty-eight hours, though in large surface wounds it remained four days.

Oxidized gauze and cotton were used in 98 cases, the best results being obtained with small pieces placed directly in the cuts. Hemostasis was aided, and the material liquefied readily so that it did not occlude drainage. Rosser used these materials in most of the common types of anal operations as well as in pilonidal wounds.

It is probably superfluous to add a word of emphasis, with which Rosser would be the first to agree, that the above devices are not a substitute, but only an adjunct to careful ligation of bleeding points, particularly arterial bleeders.

#### RELIEF OF PAIN

Mentzer<sup>13</sup> employed the oil anesthetic "anucaine" in 1510 cases, with satisfactory relief of postoperative pain and a decrease in the number of patients requiring catheterization. This particular preparation contains 0.5 per cent procaine, 1 per cent butesin, 5 per cent anesthesin, 5 per cent benzyl alcohol and as much sweet almond oil as necessary. The solution was injected through three points of entry, 2.5 cm. to the right and left of the anus and directly posterior to it, 2.5 to 5 cc. being placed in each lateral area and 5 cc. posteriorly. The solution was injected at three levels — subcutaneously

into the external sphincter and into the levator-muscle attachment. An average hospital stay of only four days and definite decrease in pain were attributed to the use of this preparation.

#### PROLAPSE OF THE RECTUM

Hayden<sup>14</sup> reviewed the experience at the Massachusetts General Hospital with the surgical treatment of complete rectal prolapse over a thirty-four-year period (1912 through 1946), with such follow-up data as could be obtained. During this period 60 patients were operated upon one or more times by 23 different surgeons, utilizing nine or ten different procedures in various combinations. The largest number of patients operated by one surgeon was 18, and the next largest 9, and so on down the line, illustrating the fact that anyone's experience is bound to be limited in this condition which is not encountered with great frequency. The Moschowitz operation (obliteration of the cul-de-sac of Douglas) was used alone or in combination with other procedures, in 43 cases. Other procedures consisted of fixation of uterus or of cervical stump, suspension of uterus or cervical stump, Mikulicz resection of sigmoid or simple fixation of sigmoid to left lateral pelvic wall, posterior fixation of rectum by various methods — Lockhart-Mummery, Tuttle and Maes-Rives — DeLorme, amputation of the prolapse by surgical excision or by compression ligature and finally, linear cauterization. Good and poor results were obtained by most of these methods, some of the best results being achieved by combined procedures. The Moschowitz operation, with or without modifications or additions, is based on a sound conception of the underlying disease, and good results may be expected, also, from use of the DeLorme operation and by excision of the prolapse.

Haves and Burr,<sup>15</sup> in reporting on 9 cases of complete rectal prolapse seen in a period of 9 years, have concluded that the procedure advocated by Graham in 1942, with a modification of their own, is an eminently satisfactory way of dealing with this condition. Graham's procedure includes an incision of the pelvic peritoneum and freeing of the rectum anteriorly and posteriorly as in abdominoperineal resection for cancer. The levators are then sutured together anteriorly. Haves and Burr modified this in 1 case by suturing the lateral ligaments across in front of the rectum, thus taking up their slack. Then, with the pelvic portion of the colon held taut, the excess peritoneum was infolded and sutured around the rectum, thus obliterating the previously deep cul-de-sac. A new bed for the sigmoid was then created by incising the lateral parietal peritoneum for 10 or 12 cm. and anchoring the taut sigmoid to the peritoneal edges raised from the deeper tissues.

Dunphy,<sup>16</sup> sharing the dissatisfaction of most surgeons about the treatment of complete prolapse, has utilized a combined abdominal and perineal

all "mucinous carcinoma" The fact that 2 of Skir's 3 patients were Negroes is also of interest because of the very low incidence of cancer of the rectum and anus in that race, as borne out by the experience of other men whose hospital clinics have a large Negro attendance

These reports are of value, and presumably the occasional development of carcinoma at the site of a chronic fistula of long duration may be considered to bear a relation to the chronic irritation of the long-continued infectious process If there is a direct relation these cases can be considered as demonstrating a good reason for dealing with fistulas reasonably promptly and eradicating them However, it seems unnecessary to resort to the fear of cancer as an argument in convincing people that their fistulas should be operated upon when the obvious inconvenience and discomfort of recurring abscesses and of intermittent or continuous drainage are sufficient reasons for instituting surgical treatment promptly

Kenney<sup>9</sup> reports his experience with a method of excision and suture of anal fistulas, carried out in 12 cases with healing in 11 and with no recurrences for follow-up periods extending from two to six months After a preoperative preparation with sulfanilamide and castor oil he carefully cuts around the external opening, after first passing a probe through the sinus, and then incises radially toward the anus but not into the tract and not across the mucocutaneous junction The sinus is dissected out, free of the muscle, after which the internal opening is encircled and the sinus removed The tissues are then infiltrated with penicillin solution, using 20 to 100 cc of a solution containing 2000 units per cubic centimeter and after careful hemostasis the wound is obliterated with fine cotton sutures in layers, the internal opening closed with fine chromic and the external opening with 80-gauge or 120-gauge cotton Patients leave the hospital in several days

This is a praiseworthy attempt to improve the technic of dealing with anal fistula and is in line with the advances made in primary union after pilonidal-sinus excisions It is perhaps only fair, however, to emphasize the difficulties encountered by many surgeons in attempts to obtain primary healing in the anal area, and it is probable that most surgeons will have a higher percentage of cures if they adhere to open incision and drainage operations

#### PRURITUS ANI

Attempts to relieve or cure pruritus of the anal region have embraced as wide a variety of therapeutic agents and methods as any pathologic condition, and yet no striking progress has been made in establishing its cause or in finding a permanent cure

Frankfeldt<sup>10</sup> calls attention to the well known fact that the majority of people with hemorrhoids, fissures, fistulas, incontinent sphincter, colitis and so forth do not complain of itching despite the fecal soiling, mucus and purulent discharge that often accompany these conditions Therefore, it seems to him logical to assume that two factors operate in people who have pruritus and a sensitization of the skin, and an irritant (allergen or antigen) With this premise he concludes that anal pruritus must be an *allergic manifestation*

A careful history, dealing with all sorts of factors that might contribute to the establishment of an allergy, is taken from each patient by means of an extensive questionnaire, and as a result Frankfeldt believes that he can classify the cases into five groups, allergic to food, fungus and bacteria, contact dermatitis, drugs and atopans

In mentioning the various substances to which an allergy might exist Frankfeldt presents a list so long that it is hard to see how anyone could escape having pruritus

He believes that histamine is in some way concerned with the problem and has employed the antihistaminic agent, pyribenzamine, in treatment, giving 50 to 150 mg after each meal and at 10 p m This plan was carried out in 90 patients with 85 to 100 per cent relief from itching in 57 Of the 57 he considered 26 to have a food allergy, 10 a fungus allergy, 12 contact dermatitis, 6 a drug allergy, and 3 an atopic dermatitis An ointment of 2 per cent pyribenzamine in a water-washable base was also used in 11 cases, with relief only in patients who had also experienced relief from oral administration of the drugs In 33 patients there was no relief

Instructions regarding hygienic measures were given to the patients in all cases

In discussion of this paper Belknap reported only 13 per cent good results in his experience with pyribenzamine, whereas Terrell emphasized the role of fungi as of prime importance

All in all proctologists are not much farther along toward a cure of pruritus ani than they were thirty years ago

Kallet<sup>11</sup> reports gratifying relief in 92 per cent of 100 cases of intractable pruritus ani subjected to a combined excision and under-cutting operation, which he calls "the clover-leaf operation" because of the appearance of the area following excision of three or four elliptical segments of perianal skin Patients selected for this procedure were all chronic cases with symptoms of long duration — up to twenty years Most of them had had various types of treatment — such as ointments, x-rays, injections and other rectal surgery The operation is best suited to patients with localized thickening, skin folds, lichenification and hypertrophy of the perianal skin

The incisions are made only up to the anal verge, not into it, and strips of skin about 0.6 cm wide are left between the elliptical incisions These bands

are then undercut. Complete closure of the wounds occurs in about a month, and Kallet advises digital dilatations of the anus periodically.

The difference between this procedure and the old undercutting operation, as advocated by Ball, lies in the excision of skin that characterizes the former, whereas in the latter little or no skin is sacrificed.

Discussion of this paper brought forth varying reactions, including emphasis on the value of subcutaneous alcohol injection as a substitute for too radical excision of skin and mention of the value of including some degree of anal-canal surgery — removal of papillae and crypts, and partial incision of the anal ring to relieve tightness — in association with the external work. Kallet, in closing the discussion, strongly urged that no intra-anal cutting be done and emphasized that in most of these cases the anal canal is found to be quite normal. In the last statement I agree with him.

#### HEMOSTATIC AGENTS

Rosser<sup>12</sup> reported, as an experimental study in 141 anorectal operations, the use of gelatin sponge (gel foam), oxidized cotton or oxidized gauze as a packing in the wounds at time of operation. Fibrin foam was not tried because of its origin in human blood, which might make it less available. Rosser cites the experimental work of several authors indicating that gelatin sponge is nonirritating and gradually absorbable. He used it in 43 anorectal wounds and found that it usually disappeared in forty-eight hours, though in large surface wounds it remained four days.

Oxidized gauze and cotton were used in 98 cases, the best results being obtained with small pieces placed directly in the cuts. Hemostasis was aided, and the material liquefied readily so that it did not occlude drainage. Rosser used these materials in most of the common types of anal operations as well as in pilonidal wounds.

It is probably superfluous to add a word of emphasis, with which Rosser would be the first to agree, that the above devices are not a substitute, but only an adjunct to careful ligation of bleeding points, particularly arterial bleeders.

#### RELIEF OF PAIN

Mentzer<sup>13</sup> employed the oil anesthetic "anucaine" in 1510 cases, with satisfactory relief of postoperative pain and a decrease in the number of patients requiring catheterization. This particular preparation contains 0.5 per cent procaine, 1 per cent butesin, 5 per cent anesthesin, 5 per cent benzyl alcohol and as much sweet almond oil as necessary. The solution was injected through three points of entry, 2.5 cm. to the right and left of the anus and directly posterior to it, 2.5 to 5 cc. being placed in each lateral area and 5 cc. posteriorly. The solution was injected at three levels — subcutaneously

into the external sphincter and into the levator-muscle attachment. An average hospital stay of only four days and definite decrease in pain were attributed to the use of this preparation.

#### PROLAPSE OF THE RECTUM

Hayden<sup>14</sup> reviewed the experience at the Massachusetts General Hospital with the surgical treatment of complete rectal prolapse over a thirty-four-year-period (1912 through 1946), with such follow-up data as could be obtained. During this period 60 patients were operated upon one or more times by 23 different surgeons, utilizing nine or ten different procedures in various combinations. The largest number of patients operated by one surgeon was 18, and the next largest 9, and so on down the line, illustrating the fact that anyone's experience is bound to be limited in this condition, which is not encountered with great frequency. The Moschowitz operation (obliteration of the cul-de-sac of Douglas) was used, alone or in combination with other procedures, in 43 cases. Other procedures consisted of fixation of uterus or of cervical stump, suspension of uterus or cervical stump, Mikulicz resection of sigmoid or simple fixation of sigmoid to left lateral pelvic wall, posterior fixation of rectum by various methods — Lockhart-Mummery, Tuttle and Maes-Rives — DeLorme, amputation of the prolapse by surgical excision or by compression ligature and, finally, linear cauterization. Good and poor results were obtained by most of these methods, some of the best results being achieved by combined procedures. The Moschowitz operation, with or without modifications or additions, is based on a sound conception of the underlying disease, and good results may be expected, also, from use of the DeLorme operation and by excision of the prolapse.

Haves and Burr,<sup>15</sup> in reporting on 9 cases of complete rectal prolapse seen in a period of 9 years, have concluded that the procedure advocated by Graham in 1942, with a modification of their own, is an eminently satisfactory way of dealing with this condition. Graham's procedure includes an incision of the pelvic peritoneum and freeing of the rectum anteriorly and posteriorly as in abdominoperineal resection for cancer. The levators are then sutured together anteriorly. Haves and Burr modified this in 1 case by suturing the lateral ligaments across in front of the rectum, thus taking up their slack. Then, with the pelvic portion of the colon held taut, the excess peritoneum was infolded and sutured around the rectum, thus obliterating the previously deep cul-de-sac. A new bed for the sigmoid was then created by incising the lateral parietal peritoneum for 10 or 12 cm. and anchoring the taut sigmoid to the peritoneal edges raised from the deeper tissues.

Dunphy,<sup>16</sup> sharing the dissatisfaction of most surgeons about the treatment of complete prolapse, has utilized a combined abdominal and perineal

operation in 4 patients, with satisfaction to the patients and to himself though the follow-up period had not exceeded a year and eight months in any of the 4 at the time he wrote the paper. The operation described combines the best features of several of the radical procedures previously in use and is done in two stages—the perineal part first. It embraces circular amputation of the external prolapse, excision of the peritoneal hernial sac so far as accessible from below, suture of the levators anteriorly, and reconstruction of the lumen of the bowel by a combination of interrupted and short continuous sutures, to eliminate or reduce the degree of narrowing at the suture line.

A week of preliminary preparation with sulfathaladine to diminish the bacterial flora in the bowel is advocated, and during this time, also, the patient is encouraged to build up sphincter tone by numerous voluntary contractions of the muscle—"a thousand times a day."

Some days later the abdomen is opened and the rectum mobilized as in the abdominoperineal resection for cancer, after which some deep sutures are placed laterally, including peritoneum and fascia and lateral ligaments. The cul-de-sac is then obliterated by pursestring sutures, as in the Moschcowitz operation, and the pelvic portion of the colon anchored to the lateral wall of the pelvis with interrupted silk sutures.

### COLITIS

Although the etiology of ulcerative colitis is still unknown, various experiments in the treatment of the disease continue to be reported in the literature. Gill<sup>17</sup> has utilized mucosa from the small intestine, particularly the jejunum, of pigs, on the theory that ulcerative colitis may be due to a deficiency of some constituent normally supplied by the mucosa of the small intestine. The mucosa is given in the form of a desiccated raw preparation, one ounce (equivalent to one pound of the original mucosa) being given daily.

Nasio<sup>18</sup> has utilized a colloidal preparation similar to the intestinal juices, giving it by the drip method. Alvarez<sup>19</sup> emphasizes the value of amino acid therapy in ulcerative colitis to make up for the loss of protein in the evacuations.

Kiefer and Jordan<sup>20</sup> presented before the American Proctologic Society an analysis of 430 cases of ulcerative colitis from the Lahey Clinic. Mention was made of the psychosomatic factor in this disease, of the unexplainable remissions and exacerbations and of its characteristic proctoscopic picture.

The proctologic complications occurring in this series consisted of perianal abscess in 12 per cent of cases, 14 strictures, 5 severe perianal skin infections and 25 cases of accompanying hemorrhoids or fissures. The authors also stated that hemorrhoidectomy had been performed in a good many

cases before they came to the clinic, presumably by surgeons who were not aware of the true diagnosis.

Adenocarcinoma developed in 7 per cent of the long-standing cases, possibly superimposed on true polyps that existed coincidentally.

In the 430 cases, the rectum alone was involved in 73, or 17 per cent. Involvement of rectum and part or all of the left portion of the colon occurred in 92 cases, or 21 per cent, and in 242 cases, or 56 per cent, the right portion of the colon was also involved. A fourth group—cases with segmental colitis and no rectal involvement—numbered 23, or 6 per cent. Medical measures in treatment were designed to control diarrhea, malnutrition, blood loss and anemia and sepsis. Emphasis was laid on the term "control" rather than "cure"—a distinction with which all agree in the management of this disease.

In the milder cases fever therapy, by means of gradually increasing doses of typhoid vaccine, has been used with gratifying results, and the elimination of causes of psychic trauma is desirable if possible.

Medical treatment in 34 cases with proctitis alone resulted in control of the disease that was good in 16, fair in 9 and poor in 9. Of 84 cases involving only the descending colon good control was obtained in 22, fair in 13 and poor in 28. In the group with generalized colitis (160 patients) the results were as follows: good control in 37, fair in 11 and poor in 77, whereas in the segmental group of 14 cases good control of the disease resulted in 5, fair in none and poor in 6.

With their experience of obtaining distinct improvement in most patients after ileostomy the authors believe that to delay this measure over a week in a patient with spiking temperature and evidence of increasing toxicity is a very risky postponement.

There were 32 "emergency" ileostomies performed, with 75 per cent mortality. For this reason every attempt is made to anticipate the need for ileostomy to avoid the necessity for an emergency procedure in a poor-risk patient. Elective ileostomy in 76 patients yielded a mortality of only 6.5 per cent.

Partial or complete colectomy was performed in 93 patients—a total of 146 different procedures—with an operative mortality of 8.2 per cent and a case mortality of 12.8 per cent.

The König-Rutzen bag is considered to be the best appliance for ileostomy control, since it is cemented to the skin and if properly applied can be made leak tight both day and night.

### POLYPS

Binkley and Sunderland<sup>21</sup> classify benign adenomas of the colon as areas of hyperplasia, adenomas and papillary adenomas—the second group

being most frequently encountered. Emphasis is laid on the uncertainty of pathological diagnosis in some cases owing to the fact that early malignant change in a small area may be easily overlooked. The importance of recognizing clinically the characteristics of malignant change is also stressed — the induration, ulceration and bleeding on slight trauma and the color of the lesion. Treatment varies with size and location of the lesion — surgical excision, removal with a snare or electrocoagulation. Radiation is reserved for the polyps that cannot be completely removed, and can be given either by external application of x-rays or by intrarectal application of radium to the surface of the lesion or in the form of gold radon seeds. Once in a while the rectum must be removed completely to eradicate a lesion, particularly if the base is suspicious of cancer.

Swinton<sup>22</sup> reported the presence of polyps in the colons of 311 of 1843 patients coming to autopsy at the New England Deaconess Hospital. In 42 of the 311 there were multiple lesions. Over 50 per cent were within reach of a 25-cm sigmoidoscope.

Of 22 cases reported in this paper, very early malignant change in the polyp but not involving the stalk was found in 12 cases, and a local removal was performed. All patients had had bleeding as a symptom. Two of these also had a later radical operation, but no cancer could be found in the specimens. Of the group, 10 had tumors in the colon — 8 in the sigmoid and 2 in the descending colon.

In 41 cases with polyps, removal was accomplished by the abdominal route. There was no evidence of malignant change in 31 of these. Bleeding

was a symptom in 38 of the 41 cases. One death occurred.

### POLYPS

Binkley and Sunderland<sup>21</sup> classify benign adenomas of the colon as areas of hyperplasia, adenomas and papillary adenomas — the second group

DR HALSTED The x-ray findings suggest gastritis, but the x-ray diagnosis of gastritis is not accurate. One can see apparent gastritis on x-ray examination and find a normal-appearing mucosa by gastroscopy, but the reverse is more generally true—that the x-ray film appears normal and gastroscopy demonstrates gastritis.

In summary, this man had a chief complaint of chronic epigastric distress for a year, with no anemia and no weight loss. There was evidence of bleeding by gastroscopy as well as by examination of fluid removed from the stomach by aspiration. Apparently he had a rather diffuse lesion that tended to involve the upper part of the stomach. This was first reported from another hospital four months before entry here. At that time he showed what was thought to be an ulcer crater in the center of the area.

From the evidence at hand it is not possible to make more than a guess at the diagnosis in this patient without surgical exploration. What are the differential possibilities? The commonest lesion that causes chronic epigastric distress at this age is peptic ulcer. I rule that out because of the achlorhydria, confirmed by two examinations and the history. Such rare lesions as tuberculosis and syphilis, which might involve the stomach, can also be discarded, since there was no evidence of these diseases elsewhere in the body. We come down to a tumor or gastritis. If it was a tumor, was it cancer or a lymphoblastoma type of tumor or possibly a benign tumor? Carcinoma is about a hundred times more common in the stomach than lymphosarcoma statistically. At this patient's age, however, it is only about fifteen times more common. Cancer of the stomach is more apt to be in the lower end, 50 per cent of cases involve the antrum and pylorus. This lesion apparently involved the upper portion of the stomach, which makes one suspect more strongly some other lesion than cancer. If he had carcinoma, with symptoms of a year's duration and with this rather extensive involvement as evidenced by gastroscopy, I should expect that he would have lost weight and be definitely anemic, neither weight loss nor anemia was mentioned, so that I should be in favor of tumor other than carcinoma, provided it was a tumor.

Could it have been gastritis? A severe hypertrophic ulcerating type of gastritis can produce this picture, both by x-ray and gastroscopic findings as well as clinically. I cannot interpret the gastroscopy, it is a subjective method of examination, and I have to rely on what the gastroscopist thought at the time. I do not imagine a biopsy was taken, there is no mention, although it is now possible to take biopsies through a new kind of flexible gastroscope. I do not know what Dr Benedict's results have been with that instrument. The achlorhydria is an important finding here. At the age of thirty, it is estimated to occur in 2

to 4 per cent of people normally. Thus the achlorhydria in a patient of thirty would almost surely be due to disease. Schindler<sup>1</sup> says that gastritis is not associated with achlorhydria as a rule, the hypertrophic type is generally associated with acid.

The suggestion of a mass that the gastroscopist reported—apparently a round mass protruding from the submucosa—may be important and suggests that this man had a tumor of the upper part of the stomach, not a carcinoma. Hodgkin's disease, restricted to the stomach and not involving other parts of the gastrointestinal tract or other parts of the body, is extremely rare. There were only 20 cases reported up to 1946. The same observation is true of leukemic infiltration of the stomach in an aleukemic phase of the disease. I would have to rule this out without any other evidence of the disease. There is nothing to suggest that this was an extragastric tumor, such as retroperitoneal sarcoma, which was compressing or invading the stomach. No mass was felt, and the x-ray report indicates that the lesion involved the stomach wall. Leiomyoma or leiomyosarcoma is usually an isolated tumor, although in rare cases it has been reported as a diffuse tumor involving the stomach. This type of tumor characteristically is without symptoms except for bouts of massive bleeding, with no digestive symptoms of pain and distress. Lymphosarcoma comprises about 40 per cent of gastric sarcomas. This may diffusely involve the stomach or may grow inward or outward as a discrete tumor.

I suppose, on statistical grounds alone, that carcinoma is perhaps the most likely diagnosis, but for the reasons I have given, I do not believe it was present. This could have been extensive hypertrophic gastritis or a lymphomatous or sarcomatous type of tumor. Gastritis is much more common, but because of the achlorhydria and the gastroscopic findings this case is more suggestive of a diffusely invading tumor, probably lymphosarcoma.

DR BENJAMIN CASTLEMAN Will you tell us what your opinion was before operation, Dr Allen?

DR ALLEN Dr Halsted has covered our line of reasoning very accurately. We were not sure that this man had a serious lesion of the stomach, but we felt that we had to explore him to find out whether there was tumor in the stomach or not. This was based to some extent on the achlorhydria and on the gastroscopic impression. We had had an almost identical picture in a patient who proved to have a lymphoma of the stomach. We have also had 2 other cases presenting the same picture but with acid in the stomach that proved to be due to giant gastritis. In these patients there was an enormous increase in the size of the rugae of the stomach.

I explored this patient with an open mind, thinking that I would have to rule out a serious surgical situation.

### CASE 34371

#### PRESENTATION OF CASE

A thirty-year-old man was admitted to the hospital because of epigastric distress.

The patient had previously been well until one year prior to admission, when he began to notice epigastric distress following large meals. This became gradually more persistent and then became consistently associated with the noonday meal. X-ray studies done at another hospital four months before entry showed a filling defect on the greater-curvature side of the pars media of the stomach surrounded by exaggerated rugae and a suspicious ulcer crater in the center of the area. Three days later a repeat examination failed to show any filling defect but there were some hypertrophied rugae on the greater curvature. Further studies one month before admission again demonstrated a questionable gastric lesion and a total achlorhydria following an alcohol test meal. He was given dilute hydrochloric acid, but the symptoms continued. There was no relation of the distress to fatty or other particular foods, and alkalies afforded no relief. Neither did eating smaller meals bring any relief from the gastric distress. He gained several pounds over the several weeks before entry. There was no change in bowel habit.

The past history and a system review were non-contributory.

Physical examination revealed a well developed and well nourished man in no distress. Examination of the lungs, heart and abdomen was entirely negative.

The blood pressure was 120 systolic, 65 diastolic. Examination of the blood disclosed a white-cell count of 8000. The hemoglobin was 13.8 gm per 100 cc. The urine was normal. Gastric analysis after an alcohol test meal showed no free hydrochloric acid in the fasting, half-hour and one-hour specimens. All three were guaiac positive. A gastrointestinal series demonstrated a normal esophagus. The stomach was situated high and transversely. Unusually large rugal folds were present in the proximal half of the stomach. The mucosal pat-

tern of the distal portion of the stomach was not abnormal, although slight mucosal thickening was possibly present. The mucosa in the upper half appeared to be coated with foreign material, and the pattern was mottled. The walls of the stomach were pliable. The duodenal bulb was not remarkable.

Gastroscopy was done, and the gastroscope readily passed. The angulus was somewhat rigid, and no peristalsis was seen. There was not the usual response to air inflation. Only the proximal portion of the antrum was visualized, and the distal antrum and pylorus were not seen. Throughout the body of the stomach, particularly on the posterior wall and greater curvature, the rugae were very thick and tortuous. The wall of the stomach was also somewhat rigid and did not respond to air inflation. The mucosa was markedly hemorrhagic throughout the body of the stomach and bright-red blood apparently oozed from the posterior wall and greater curvature. A similar appearance was present to a lesser extent on the lesser curvature. At times there appeared to be an inconstant, round, submucosal mass on the greater curvature in the lower part of the body of the stomach.

Following these diagnostic procedures an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. JAMES A. HALSTED: I should like to ask Dr. Allen about this man's total weight loss. It is not clear.

DR. ARTHUR W. ALLEN: It is my impression that he had regained all the weight he had lost before he came to operation.

DR. HALSTED: In other words, he had a year's symptoms without any essential weight loss.

DR. ALLEN: He was certainly well nourished at the time of operation.

DR. HALSTED: Is there any record of a stool examination?

DR. ALLEN: The stools were guaiac negative.

DR. HALSTED: During gastroscopy, "there was not the usual response to air inflation." I believe that refers to the fact that with the usual response one might expect peristalsis to develop as a result of inflating the stomach. The fact that the pylorus was not seen is not surprising. In 50 per cent of gastroscopies one cannot see the pylorus.

Are the x-ray films available?

DR. JAMES McCORT: This examination shows the widening of the rugal folds, which appears mainly in the fundus of the stomach, extending down into the body of the stomach. According to the fluoroscopist's note, he was able to discover no rigidity or loss of pliability by palpation.

DR. HALSTED: The lower end is normal?

DR. McCORT: The rugal pattern in the lower end of the stomach is not altered.

## DIFFERENTIAL DIAGNOSIS

DR EARLE M. CHAPMAN I think we should start out by seeing the x-ray films

DR STANLEY M. WYMAN The mass described is well seen in the right-upper-lung field in the posteroanterior view, lying far posteriorly, and not very well seen in the lateral film. The heart shadow is definitely enlarged, probably chiefly left ventricular, and the aorta is tortuous as described. The pulmonary vascular shadows are, I think, slightly increased in prominence, suggesting some vascular engorgement. There is no evidence of rib erosion and no evidence of involvement of the chest wall itself.

DR CHAPMAN The pyelograms were done to exclude kidney tumor, I assume.

DR WYMAN The kidneys seem to be normal. The calyceal pattern shows no abnormality. The bladder shadow is not included on the film. This is the opaque material in both buttocks.

DR CHAPMAN There is no osteoporosis?

DR WYMAN Nothing significant.

DR CHAPMAN It seems to me that we are faced squarely with a differential diagnosis of a circumscribed, well outlined mass in the right-upper-lung field, not eroding bone, and not connected with the vascular system. In my simplicity, I would say that it boils down to a differential diagnosis between one of two diseases: gumma or malignant tumor of some type. From the clinical course and what happened to the patient I assume that the previous group of physicians in charge of him considered that the chance of a malignant tumor was greater than that of syphilis and advised operation. However, my reasoning, now that it is all over, is somewhat different. I think the weight of evidence rather favors syphilis of the lung and not a malignant lesion. Of course it could have been a malignant melanoma. We know that metastases occur years after the eye is originally enucleated. I think that we have to accept the other clinical signs and evidence of active syphilis. I would point out also that certain negative signs favor this as well. The absence of symptoms in this man, notably the lack of symptoms referable to the lungs, and the fact that cytologic smears failed to show cancer cells are against cancer. As you know syphilis of the lung is extraordinarily rare. We seldom see it here. In a large autopsy series, 2800 I believe, Osler\*

found only 12 cases of syphilis of the lung. It is not too uncommon in the congenital form in the infant, but in adults it is rare. Cases have been described that fall into three categories: syphilitic pneumonitis with a stenosing lesion of the bronchus, a fibrosing lesion within the lung that can simulate tuberculosis often to the point of cavity formation and the single gummatous form that may or may not have cavitation within it from necrosis. I cannot help feeling that this patient had syphilis, which was not thoroughly treated, that he had syphilitic heart disease, with aortic regurgitation and syphilitic aortitis, and that this lesion in the chest could perfectly well have been syphilis.

The physician obviously was looking for other sources. Hypernephroma is a possibility. I remember a patient who had a lymphoma removed four or five years before he came back with a single lesion in the lung. He did not have syphilis. I decided it was metastatic, the original lesion had been removed previously. He did nicely for a month but finally died with metastases in the brain.

I wonder why the clinicians did not try anti-syphilitic treatment. If it had been syphilis, it should have responded to iodides, arsphenamine or mercury. I do not know whether this was a recent case, but it seems that such a program of treatment should have been tried before operation.

A PHYSICIAN Do you think it could have been a tuberculoma, in which case the iodides would not be used?

DR CHAPMAN No, I do not. I thought of tuberculosis, but the patient had no fever, no elevated white-cell count, and no mention of the tuberculin test, and I cannot believe that it entered the minds of those taking care of him. I think they thought so strongly of its being a malignant tumor that they went ahead and removed it. But I think in view of the evidence of syphilis in the heart that it could have been a late manifestation of the disease. I do not know how I can arrive at a better diagnosis than one of those two. I cannot believe that it was pulmonary infarction. He had injection treatment for "calf pains." Did he have thromboembolic disease throwing off an embolus? I have never seen an infarct in a lung look like that, so I exclude embolic disease in the lung. Failure of progression of symptoms is against the diagnosis of cancer.

## CLINICAL DIAGNOSIS

Gastric tumor

DR HALSTED'S DIAGNOSIS

Lymphosarcoma of stomach

## ANATOMICAL DIAGNOSIS

*Chronic gastritis, superficial type, superimposed on hypertrophic type*

## PATHOLOGICAL DISCUSSION

DR ALLEN At operation the stomach was, as you can see, very high and difficult to palpate. This man was quite fat. Not being satisfied with palpation of the stomach from the outside, I opened the anterior wall of the stomach and put one hand inside the stomach and with my other hand outside I could feel the entire stomach throughout and be sure that the patient had no tumor. He did have huge rugae, and we took out a section, perhaps not so high as we would have liked but high enough we thought to include a portion that would be diagnostic. The stomach was then closed, and the abdomen closed — just a biopsy was done.

DR CASTLEMAN The microscopical sections showed a definite and characteristic chronic gastritis. Normally the glands in the fundic portion of the stomach are composed of cells whose nucleus is basally situated, the rest of the cell being filled with large amounts of mucin. Also, in the normal stomach there is a variably cellular infiltration of plasma cells, lymphocytes and eosinophils between and in the glands in the neck zone of the mucosa. Some years ago Drs Benedict and Mallory<sup>2</sup> reviewed our gastric material and determined about how much cellular infiltration in the various parts of the stomach was within physiologic limits.

In this particular case, instead of the normal type of epithelium, the glands had lost their mucin secretion, the cells were smaller, and the cytoplasm was dense. Function was obviously disturbed. There was an intense cellular infiltration, polymorphonuclears predominating, involving the upper part of the mucosa, much more than is seen normally. This form of gastritis is called superficial gastritis, and it may be superimposed on the hypertrophic or atrophic form. I believe that this is an example of acute and chronic gastritis of the superficial type superimposed on the hypertrophic form.

DR HALSTED According to Schindler<sup>1</sup> the superficial type of gastritis is much more commonly associated with achlorhydria than the chronic hypertrophic gastritis, that is probably the explanation of the achlorhydria in this case.

## CASE 34372

## PRESENTATION OF CASE

A seventy-year-old retired merchant entered the hospital on his physician's advice following x-ray studies revealing a mass in the right lung.

For the past fourteen years the patient had had frequent checkups for a cardiac condition, although his only symptom was slight exertional dyspnea. He had noticed no edema, orthopnea or weakness, but had been told a few years previously that his blood pressure was low. One year previous to admission a routine chest x-ray film revealed a mass in the right lung. Five months later x-ray study showed essentially the same picture, but in an examination two months prior to admission a slight change in the mass was noted and he was referred here. During the past year he had been asymptomatic, with no weight loss, chest pain, fever or remarkable upper respiratory infection. During this time cytologic smears of the sputum were twice reported negative.

Fifteen years prior to admission an enucleation of the left eye had been done for a malignant melanoma. About ten years prior to entry he had received injections for "calf pains."

Physical examination revealed a heart enlarged to the upper limit of normal. A long systolic and a short diastolic murmur, not widely transmitted, were heard in the aortic area. The peripheral pulses were of the Corrigan type.

The blood pressure was 200 systolic, 65 diastolic. Examination of the blood disclosed a hemoglobin of 15.8 gm and a white-cell count of 7600, with 61 per cent neutrophils, 26 per cent lymphocytes, 6 per cent monocytes and 4 per cent eosinophils. A urinalysis was negative. The serum nonprotein nitrogen was 33 mg, and the protein 7 gm per 100 cc. A cytologic smear of the sputum was negative. Blood Hinton and Wassermann tests were positive.

X-ray films of the chest showed a slightly lobulated mass of homogeneous increased density within the posterior segment of the right upper lobe overlying the right fifth, sixth and seventh ribs posteriorly. The mass was approximately 5 cm in diameter, although it lay against the posterior wall; there was no evidence of erosion. The heart was somewhat prominent in the region of the left ventricle, and the aorta was tortuous. There were areas of calcification in the mediastinum. Intravenous pyelogram showed prompt excretion in fair concentration, outlining grossly normal-appearing calyces, pelves and ureters. The bladder shadow was not remarkable. There was opaque material in both buttocks. The bones of the pelvis and lumbar spine were not remarkable. An electrocardiogram was consistent with left ventricular strain and hypertrophy.

On the eighth hospital day an operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR EARLE M. CHAPMAN I think we should start out by seeing the x-ray films

DR STANLEY M. WYMAN The mass described is well seen in the right-upper-lung field in the posteroanterior view, lying far posteriorly, and not very well seen in the lateral film. The heart shadow is definitely enlarged, probably chiefly left ventricular, and the aorta is tortuous as described. The pulmonary vascular shadows are, I think, slightly increased in prominence, suggesting some vascular engorgement. There is no evidence of rib erosion and no evidence of involvement of the chest wall itself.

DR CHAPMAN The pyelograms were done to exclude kidney tumor, I assume.

DR WYMAN The kidneys seem to be normal. The calyceal pattern shows no abnormality. The bladder shadow is not included on the film. This is the opaque material in both buttocks.

DR CHAPMAN There is no osteoporosis?

DR WYMAN Nothing significant.

DR CHAPMAN It seems to me that we are faced squarely with a differential diagnosis of a circumscribed, well outlined mass in the right-upper-lung field, not eroding bone, and not connected with the vascular system. In my simplicity, I would say that it boils down to a differential diagnosis between one of two diseases: gumma or malignant tumor of some type. From the clinical course and what happened to the patient I assume that the previous group of physicians in charge of him considered that the chance of a malignant tumor was greater than that of syphilis and advised operation. However, my reasoning, now that it is all over, is somewhat different. I think the weight of evidence rather favors syphilis of the lung and not a malignant lesion. Of course it could have been a malignant melanoma. We know that metastases occur years after the eye is originally enucleated. I think that we have to accept the other clinical signs and evidence of active syphilis. I would point out also that certain negative signs favor this as well. The absence of symptoms in this man, notably the lack of symptoms referable to the lungs, and the fact that cytologic smears failed to show cancer cells are against cancer. As you know syphilis of the lung is extraordinarily rare. We seldom see it here. In a large autopsy series, 2800 I believe, Osler\*

found only 12 cases of syphilis of the lung. It is not too uncommon in the congenital form in the infant, but in adults it is rare. Cases have been described that fall into three categories: syphilitic pneumonitis with a stenosing lesion of the bronchus, a fibrosing lesion within the lung that can simulate tuberculosis often to the point of cavity formation and the single gummatous form that may or may not have cavitation within it from necrosis. I cannot help feeling that this patient had syphilis, which was not thoroughly treated, that he had syphilitic heart disease, with aortic regurgitation and syphilitic aortitis, and that this lesion in the chest could perfectly well have been syphilis.

The physician obviously was looking for other sources. Hypernephroma is a possibility. I remember a patient who had a lymphoma removed four or five years before he came back with a single lesion in the lung. He did not have syphilis. I decided it was metastatic, the original lesion had been removed previously. He did nicely for a month but finally died with metastases in the brain.

I wonder why the clinicians did not try anti-syphilitic treatment. If it had been syphilis, it should have responded to iodides, arsphenamine or mercury. I do not know whether this was a recent case, but it seems that such a program of treatment should have been tried before operation.

A PHYSICIAN Do you think it could have been a tuberculoma, in which case the iodides would not be used?

DR CHAPMAN No, I do not. I thought of tuberculosis, but the patient had no fever, no elevated white-cell count, and no mention of the tuberculin test, and I cannot believe that it entered the minds of those taking care of him. I think they thought so strongly of its being a malignant tumor that they went ahead and removed it. But I think in view of the evidence of syphilis in the heart that it could have been a late manifestation of the disease. I do not know how I can arrive at a better diagnosis than one of those two. I cannot believe that it was pulmonary infarction. He had injection treatment for "calf pains." Did he have thromboembolic disease throwing off an embolus? I have never seen an infarct in a lung look like that, so I exclude embolic disease in the lung. Failure of progression of symptoms is against the diagnosis of cancer.

DR F DENNETTE ADAMS In my opinion, this lesion was too well defined in outline to be syphilitic. Syphilis of the lung is rare. This lesion was so typical of tumor in its appearance that I should definitely make a diagnosis of a metastatic lesion from the original disease of the eye even at this late date. The syphilis was probably purely incidental. Dr Wyman has just whispered in my ear that from the x-ray standpoint it could also have been a bronchiogenic carcinoma. I want to ask him a question. Does he believe that a bronchiogenic carcinoma of that size could have developed without any pulmonary symptoms or signs?

DR WYMAN We followed a patient with proved bronchiogenic carcinoma in the Thoracic Clinic for five years. The lesion was in the left lower lobe posteriorly, close to the chest wall, and sharply defined. It was thought to be inoperable metastatic carcinoma for a long time. This lesion was observed and filmed every few months, and during this entire time it grew very slowly and was symptomless.

From the x-ray point of view this lesion is consistent with metastatic disease or bronchiogenic carcinoma. I would not guess melanoma unless I knew about the eye. It is also quite typical of a hypernephroma.

DR CHAPMAN Would you think that it would occlude the bronchus and produce signs?

DR DAVID G FREIMAN Adenocarcinomas of the bronchus, usually seen in the peripheral portions of the lung, involve the smaller bronchial radicles and often give no clinical evidence of occlusion.

DR CHAPMAN I do not see how the clinician could make a diagnosis except after an adequate trial of antisyphilitic treatment.

DR ADAMS In the presence of aortic disease, however, one has to go slowly with antisyphilitic treatment. One might not want to wait so long to

find out. I believe operation was the correct procedure and that metastatic disease of the lung is the correct diagnosis.

#### CLINICAL DIAGNOSIS

Malignant tumor, metastatic?, primary?

#### DR CHAPMAN'S DIAGNOSES

Syphilis of the lung

Melanotic sarcoma, metastatic?

#### ANATOMICAL DIAGNOSIS

*Metastatic malignant melanoma of lung*

#### PATHOLOGICAL DISCUSSION

DR FREIMAN The operation performed was a lobectomy. We received the right upper and right middle lobes of the lung, and in the right upper lobe there was an apparently encapsulated tumor nodule, 5 cm in diameter. The outer portion was pale, and the central portion quite black. On section this proved to be a typical metastatic malignant melanoma. We were able to obtain a section of the eye previously removed, and this showed a tumor identical in appearance with that in the lung. As has been noted, the appearance of such metastases may be long delayed and intervals of ten to fifteen years have been described following enucleation of the involved eye.

A PHYSICIAN Is the metastasis usually single?

DR FREIMAN Metastases may be single or widely disseminated.

DR J GORDON SCANNELL Although a syphilitic lesion of the lung was considered preoperatively, we felt that the evidence for tumor that had increased during the past year was convincing. On seeing the patient one could not help thinking that this might have been a variation of the classic theme of a glass eye and a lump in the abdomen.

## ALLEGED PENICILLIN-RESISTANT GONORRHEA

AFTER a few years of the widespread and successful use of the sulfonamides in the treatment of acute gonorrhea, it was recognized by many observers that an increasing proportion of cases failed to respond to these drugs. Thus, during the year 1941, the late Oscar F. Cox<sup>1</sup> obtained unquestionable sulfonamide cures in 70 per cent of all male patients admitted to the Boston Dispensary with active gonococcal infections, whereas of similar cases admitted during 1944, clean-cut sulfonamide cures occurred in only 28 per cent, a complete reversal of the 1941 figure. Laboratory data in these cases indicated that the failures resulted from the resistance of the organisms and not from any change in the host. An increase in the prevalence of sulfonamide-resistant strains of *Neisseria gonor-*

*rhoeae* from 15 to 59 per cent in fifteen months was observed in Glynn County, Georgia, after the extensive use of the sulfonamides as a part of a special program for the control of gonorrhea.<sup>2</sup>

In Sweden, similar results were recorded in the same period. Seeberg,<sup>3</sup> in a report on 3428 cases of uncomplicated acute gonorrhea, mostly in males, observed that recurrences of infections after a single intensive course of sulfathiazole rose from 15 per cent early in 1941 to between 70 and 80 per cent at the end of 1943 and early in 1944. In women, the comparable failure rate was 30 per cent early in 1943 and 70 per cent at the end of the same year.

Several laboratory studies<sup>4-6</sup> have indicated that there is a fairly close correlation between the in vitro susceptibility of gonococci to sulfonamides and the clinical response of the patients to these drugs.

The gonococcus is one of the most susceptible organisms to the action of penicillin. The sensitivity of different strains of this organism—that is, the concentration of penicillin required to inhibit growth in the test tube—has varied somewhat depending on the methods used. The great majority of strains have been found by most workers to be completely inhibited by penicillin in concentrations well below 0.1 units per cubic centimeter and usually below 0.02 units per cubic centimeter.<sup>7-9</sup> Sulfonamide-susceptible and sulfonamide-resistant strains are equally sensitive to penicillin.<sup>7, 10</sup> In vitro, it is possible to enhance the resistance of the gonococcus to penicillin, but apparently this is not accomplished easily and the limit is soon reached at a moderate level even under optimum conditions. Thus, Miller and Bohnhoff<sup>11</sup> succeeded in raising the resistance of one strain so that it grew in 7.7 units per cubic centimeter by repeated transfers in penicillin-containing mediums and also caused the same organism to grow in 21 units per cubic centimeter by making alternate transfers in penicillin-free mediums. The maximum concentration of penicillin in which Bahn, Ackerman and Carpenter<sup>12</sup> got their strains of gonococci to grow in vitro was 2 units per cubic centimeter.

With the almost universal use of penicillin in the treatment of gonococcal infections, it was expected that penicillin-resistant gonococci would

sooner or later become disseminated. This has not yet been observed on any large scale, but cases of gonorrhea that are clinically resistant to treatment with even large doses of penicillin have been reported. Thus, Pulaski<sup>13</sup> reported 9 cases of penicillin-resistant gonorrhea successfully treated with streptomycin. The bacteriologic observations in these cases, however, were inadequate since they were mostly controlled by smears and the identity of the organisms was not checked by cultural methods.

Franks<sup>14</sup> reported 4 cases successfully treated with penicillin, sulfonamides and fever therapy after repeated large doses of penicillin had failed. The organisms in these 4 cases were tested by a method in which 2 drops of penicillin solution, each containing 400 units, were put into a glass cylinder within a chocolate-agar plate that was seeded with the organisms, and no zone of inhibition of growth was noted. However, no data concerning control cultures were given, and it is not known if any of the penicillin actually diffused into the agar. If the author's interpretation is correct, his findings indicate that these 4 strains were resistant to approximately 8000 units per cubic centimeter. This is extremely unlikely, and the findings can be interpreted as probably due to the result of an error either in the identity of the strains or in the determination of their sensitivity.

In another study by Duemling and Horton,<sup>15</sup> 24 cases of penicillin-resistant gonorrhea were presented in which the organisms were tested by a "gutter-strip" blood-agar plate or similar method. The gonococci were said to be resistant to 5 units of penicillin per cubic centimeter, and in 1 case to 20 units. Interestingly enough, in 4 out of 5 cases in which the organism was retested after a lapse of five to nine days, during which the patient was treated with sulfonamides, the organism had lost its penicillin resistance. Treatment with sulfathiazole or sulfadiazine and then with penicillin resulted in a complete bacteriologic cure in these 24 cases. In this instance also, the results of the sensitivity tests of control strains from cases responding to the usual course of penicillin treatment are not given nor are there complete details concerning the identity of the strains of gonococci. The findings in these and similar reports are there-

fore open to question, particularly because of the great discrepancy in the quantitative estimation of sensitivity in view of the comparative difficulty of experimentally inducing high degrees of resistance in authentic strains of gonococci.

Three recent reports shed further light on the validity of the bacteriologic findings and on the interpretations in the alleged cases of penicillin-resistant gonorrhea. Parkhurst, Harb and Cannefax,<sup>16</sup> in an attempt to study such cases, deliberately accepted cases of alleged penicillin-resistant gonorrhea for treatment at the Hot Springs Medical Center. In addition, they invited the Arkansas Board of Health to refer all cases of penicillin-resistant gonorrhea to them from the local health units. In a study of over 3000 cases in males and females, including those referred as penicillin-resistant cases, they did not encounter a single case in which adequate penicillin dosage did not render the patient culturally free of the gonococcus. They believed that they had good reason to question the reliability of the diagnosis of penicillin-resistant gonorrhea based only on the clinical response and on findings in bacteriologic smears. They also believed that adequate cultural methods, including tests of the biochemical reactions and penicillin sensitivity of the organism, should be carried out before a case was diagnosed as penicillin-resistant gonorrhea. They were firmly convinced that the urethral discharges that occurred after penicillin treatment were the result of nongonococcal or nonspecific infections.

Hughes and Carpenter<sup>17</sup> studied 216 soldiers referred to them from the Pacific Theater and from the Zone of the Interior as penicillin-resistant cases of gonorrhea. They found 86 of these cases to be completely asymptomatic, and only 117, or 56 per cent, had any urethral exudate. Bacteriologic studies of the latter cases revealed that only 19, or 9 per cent, were positive for a gonococcus, 16 by culture of the anterior urethral discharge and 3 only by smears. Cultures of the latter 3 and of the urinary sediments of all 19 were negative for gonococcus. The predominant organism in these cases was an alpha streptococcus in 41, a hemolytic or anhemolytic staphylococcus in 51 and miscellaneous organisms in some of the others. Only 6 of the gonococcus cultures could be main-

tained satisfactorily for sensitivity tests. These were all found to be sensitive to concentrations ranging from 0.01 to 0.08 units, a range similar to that usually reported by others as already noted. Treatment of the 19 cases with a single dose of 300,000 units of calcium penicillin in beeswax and peanut oil resulted in complete clearing of the exudate in twenty-four to seventy-two hours in 14 cases. The remaining 5 patients showed no improvement in twenty-four hours, but they were rendered completely asymptomatic in another forty-eight hours after a second dose of the same amount of penicillin. These authors concluded that penicillin-resistant gonorrheal urethritis is usually nongonococcal urethritis erroneously diagnosed because of unsatisfactory bacteriologic methods.

Finally, Hawks and Greer<sup>13</sup> tested 330 strains of gonococci—64 from the prepenicillin days and the rest from recent cases. The sensitivity of the strains in both groups was the same, all were inhibited by 0.06 units of penicillin, or less, per cubic centimeter.

Cases of acute gonorrhea may respond to streptomycin in moderate doses.<sup>13, 19</sup> It is very likely, however, that many of the cases that have been considered clinically to be penicillin-resistant gonorrhea, particularly the uncomplicated cases of urethritis that responded promptly to streptomycin, are actually cases of nongonococcal infection in which the organism is susceptible to streptomycin. It is of considerable theoretical interest as well as of practical importance to determine for certain whether or not there are any penicillin-resistant strains of gonococci prevalent in the community and whether or not their numbers are increasing. Physicians who encounter cases of infection in which the presence of such penicillin-resistant gonococci is suspected should make every effort to obtain proper cultures or see that such cultures are made in laboratories where there is sufficient interest and where facilities are available for the proper identification of the strains and the determination of their sensitivity to the antibiotic.

#### AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

THE American Association for the Advancement of Science will hold its Centennial Meeting in Washington, D C, September 13 to 17, 1948. The morning programs will consist of technical symposiums on important scientific problems, the evening sessions, after the first evening, will be devoted to semipopular lectures that will be open to the general public. Two addresses will be given at the first evening meeting, by the President of the United States and by the retiring president of the Association, Dr Harlow Shapley.

A hundred years ago on September 20, 1848, the first meeting of this distinguished society was called to order in the library room of the Academy of Natural Sciences of Philadelphia by Professor William B Rogers, of Virginia. Professor Walter R Johnson, of Washington, served as secretary, and with the assistance of a special committee collected the proceedings of the sessions in a volume of 156 pages.

sooner or later become disseminated. This has not yet been observed on any large scale, but cases of gonorrhea that are clinically resistant to treatment with even large doses of penicillin have been reported. Thus, Pulaski<sup>13</sup> reported 9 cases of penicillin-resistant gonorrhea successfully treated with streptomycin. The bacteriologic observations in these cases, however, were inadequate since they were mostly controlled by smears and the identity of the organisms was not checked by cultural methods.

Franks<sup>14</sup> reported 4 cases successfully treated with penicillin, sulfonamides and fever therapy after repeated large doses of penicillin had failed. The organisms in these 4 cases were tested by a method in which 2 drops of penicillin solution, each containing 400 units, were put into a glass cylinder within a chocolate-agar plate that was seeded with the organisms, and no zone of inhibition of growth was noted. However, no data concerning control cultures were given, and it is not known if any of the penicillin actually diffused into the agar. If the author's interpretation is correct, his findings indicate that these 4 strains were resistant to approximately 8000 units per cubic centimeter. This is extremely unlikely, and the findings can be interpreted as probably due to the result of an error either in the identity of the strains or in the determination of their sensitivity.

In another study by Duemling and Horton,<sup>15</sup> 24 cases of penicillin-resistant gonorrhea were presented in which the organisms were tested by a "gutter-strip" blood-agar plate or similar method. The gonococci were said to be resistant to 5 units of penicillin per cubic centimeter, and in 1 case to 20 units. Interestingly enough, in 4 out of 5 cases in which the organism was retested after a lapse of five to nine days, during which the patient was treated with sulfonamides, the organism had lost its penicillin resistance. Treatment with sulfathiazole or sulfadiazine and then with penicillin resulted in a complete bacteriologic cure in these 24 cases. In this instance also, the results of the sensitivity tests of control strains from cases responding to the usual course of penicillin treatment are not given nor are there complete details concerning the identity of the strains of gonococci. The findings in these and similar reports are there-

fore open to question, particularly because of the great discrepancy in the quantitative estimation of sensitivity in view of the comparative difficulty of experimentally inducing high degrees of resistance in authentic strains of gonococci.

Three recent reports shed further light on the validity of the bacteriologic findings and on the interpretations in the alleged cases of penicillin-resistant gonorrhea. Parkhurst, Harb and Cannefax,<sup>16</sup> in an attempt to study such cases, deliberately accepted cases of alleged penicillin-resistant gonorrhea for treatment at the Hot Springs Medical Center. In addition, they invited the Arkansas Board of Health to refer all cases of penicillin-resistant gonorrhea to them from the local health units. In a study of over 3000 cases in males and females, including those referred as penicillin-resistant cases, they did not encounter a single case in which adequate penicillin dosage did not render the patient culturally free of the gonococcus. They believed that they had good reason to question the reliability of the diagnosis of penicillin-resistant gonorrhea based only on the clinical response and on findings in bacteriologic smears. They also believed that adequate cultural methods, including tests of the biochemical reactions and penicillin sensitivity of the organism, should be carried out before a case was diagnosed as penicillin-resistant gonorrhea. They were firmly convinced that the urethral discharges that occurred after penicillin treatment were the result of nongonococcal or nonspecific infections.

Hughes and Carpenter<sup>17</sup> studied 216 soldiers referred to them from the Pacific Theater and from the Zone of the Interior as penicillin-resistant cases of gonorrhea. They found 86 of these cases to be completely asymptomatic, and only 117, or 56 per cent, had any urethral exudate. Bacteriologic studies of the latter cases revealed that only 19, or 9 per cent, were positive for a gonococcus, 16 by culture of the anterior urethral discharge and 3 only by smears. Cultures of the latter 3 and of the urinary sediments of all 19 were negative for gonococcus. The predominant organism in these cases was an alpha streptococcus in 41, a hemolytic or anhemolytic staphylococcus in 51 and miscellaneous organisms in some of the others. Only 6 of the gonococcus cultures could be main-

and the consequent consumption of walrus meat, although there was reason for suspecting also the white whale

Bizarre phenomena still occur in nature, and one is repeatedly reminded that God moves in a mysterious way in the performance of His wonders. There is no evidence that the walruses of Greenland have ever been implicated in the fantastic social and gastronomic relations described by Carroll,<sup>3</sup> but one may wonder if the oysters on which they might have fed had had their prescribed veterinary inspection.<sup>4</sup>

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### RHEUMATIC-FEVER FELLOWSHIPS

The United States Children's Bureau has made available through the Massachusetts Department of Public Health and Harvard Medical School two fellowships in rheumatic fever at the House of the Good Samaritan of the Children's Medical Center, Boston, for the year 1948, beginning immediately.

Trainees should be interested in working eventually in the field of rheumatic fever in public health or in teaching, rather than in private practice.

Work under these fellowships probably will be acceptable for credit by the Board of Internal Medicine or the Board of Pediatrics.

Application should be made to Dr. Benedict F. Massell at the House of the Good Samaritan, 25 Binney Street, Boston 15, or by telephone call to BEacon 2-3002.

### ADMISSION OF CRIPPLED CHILDREN TO LAKEVILLE STATE SANATORIUM

The Department of Public Health announces that under the provisions of Chapter 412 Acts of 1948, it has been authorized to admit to Lakeville State Sanatorium certain crippled children provided that they have been residents of the Commonwealth for at least twelve months preceding the date of application for admission. Prior to the passage of this act Lakeville Sanatorium had been authorized to admit only patients with extrapulmonary forms of tuberculosis and persons crippled with infantile paralysis.

Because of the steady decline in extrapulmonary forms of tuberculosis, beds are now available for

the treatment of other orthopedic conditions, and this act will make these facilities available for indigent children for whom the Commonwealth cannot provide necessary treatment in general hospitals.

Crippling conditions, including cerebropastic palsy, spina bifida, clubfoot, congenital dislocations and deformities, obstetric paralysis, osteomyelitis, osteochondritis, epiphysitis and scoliosis, are considered suitable for treatment at Lakeville.

Applications for admissions of crippled children may be filed by any registered physician with the Massachusetts Department of Public Health, Room 546, State House, Boston.

### COMMUNICABLE DISEASES IN MASSACHUSETTS FOR JULY, 1948

#### RÉSUMÉ

DISEASES	JULY 1948	JULY 1947	SEVEN-YEAR MEDIAN
Chancroid	4	2	2*
Chicken pox	619	664	516
Diphtheria	15	19	14
Dog bite	1517	1116	1229
Dysentery bacillary	9	11	11
German measles	61	52	116
Gonorrhea	284	352	56
Granuloma inguinale	0	0	1*
Lymphogranuloma venereum	0	0	2*
Malaria	4	1	15
Measles	2462	616	1159
Meningitis meningococcal	5	7	13
Meningitis Pfeiffer-bacillus	4	1	2
Meningitis pneumococcal	2	2	2†
Meningitis, staphylococcal	0	0	0†
Meningitis streptococcal	0	0	0†
Meningitis other forms	2	0	0†

Typhoid fever	1	1	4
Undulant fever	1	6	4
Whooping cough	10	551	562

\*Four year median

†Six-year median

#### COMMENT

Diseases with an incidence above the seven-year median were chicken pox, diphtheria, measles, mumps, lobar pneumonia, scarlet fever and undulant fever.

Diseases with an incidence below the seven-year median were bacillary dysentery, German measles, poliomyelitis and whooping cough.

The apparent increase in lobar pneumonia was due to delayed hospital reporting.

July had the highest incidence for mumps since 1915, whooping cough showed the lowest incidence since 1915.

#### GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Actinomycosis was reported from Brockton, 1, total, 1.

Diphtheria was reported from Athol, 1, Berkley, 2, Boston, 8, Braintree, 1, Cambridge, 1, Revere, 1, Weymouth, 1, total, 15.

Dysentery, bacillary, was reported from Dedham, 1, Waltham, 1, Worcester, 6, Wrentham, 1, total, 9.

Encephalitis, infectious, was reported from Hudson, 1, Milford, 1, Worcester, 1, total, 3.

Lymphocytic chorion meningitis was reported from Cambridge, 1, total, 1.

Malaria was reported from Greenfield, 1, Medford, 1, Revere, 1, Springfield, 1, total, 4.

Meningitis, meningococcal, was reported from Boston, 2, Brookline, 1, Cambridge, 1, Winchester, 1, total, 5.

Meningitis, Pfeiffer-bacillus was reported from East Bridgewater, 1, Marlboro, 1, Revere, 1, Salem, 1, total, 4.

Meningitis, pneumococcal, was reported from Boston, 1, Worcester 1, total, 2.

The origin and the organization of the Association were duly recorded " 'In conformity with a resolution of the Association of American Geologists and Naturalists,' adopted during its session at Boston in September, 1847, that body agreed to resolve itself into the American Association for the Advancement of Science "

The first president of the Association, William C Redfield, Esq., of New York, assumed office that afternoon. The first paper of the meeting was forthwith read by Peter A. Brown, L.L.D., on *Some Notice of the Fossil Cephalopodes Belemnosepia, Long Known by the Name of 'Belemnite,' and of the Diphosphate of Iron, called 'Mullicite,' Found Together at Mullica Hill*

The *Journal* wishes long life and continued prosperity to the American Association for the Advancement of Science. The next hundred years should be easier.

## BARUCH COMMITTEE REPORT

CONTINUED progress in the development of physical medicine and facilities for the rehabilitation of the sick and disabled is indicated in the annual report of the Baruch Committee on Physical Medicine, recently released. The Committee was founded by Mr. Bernard M. Baruch in 1944 in memory of his father, Dr. Simon Baruch, a pioneer in physical medicine.

According to this report, the committee has already achieved its major objectives of increasing the number of physicians trained to teach and use the methods of physical medicine, of providing facilities for more extensive research in physical medicine and for "insuring the proper use of physical medicine in relation to wartime rehabilitation and peacetime physical preparedness."

There are now, according to Dr. Frank H. Krusen, director of the Committee and director of physical medicine at the Mayo Foundation, approximately 150 communities in the country that have or are planning civilian rehabilitation programs. Already many of the rehabilitation services in Veterans Administration, Army and Navy hospitals are directed by physicians whose training the Baruch Committee sponsored.

As further evidence of an increased awareness of the need of opportunities for rehabilitation, the seventy residencies and fellowships now available at thirty-four medical centers may be compared with the five such appointments available five years ago. Today sixty medical schools instead of the thirty that existed before the Committee was organized offer instruction in physical medicine.

The need for an organized rehabilitation program has long existed. Four years of war increased the need and conditioned the public in its favor. The labors of the Baruch Committee and the generosity of its founder have provided much of the actual power for accomplishment.

## STRANGE HOST

AN interesting sidelight on the part that wild life may play in man's destiny has been exposed by Thorborg and his associates<sup>1</sup> and made the subject of an annotation in the *Lancet*.<sup>2</sup>

It appears that in May, 1947, the State Serum Institute in Copenhagen was made aware of a mysterious epidemic that had broken out in Greenland. During the previous five months about 300 cases of an acute and distressing malady had occurred, with a 10 per cent mortality. The disease usually began gradually although sometimes the onset was acute. Progressive lassitude became evident with headache, pains in limbs and trunk, and fever, slight at first, then rising to considerable heights. Gastrointestinal symptoms developed, and edema of the face, limbs or entire body was an almost constant feature. The cases of sudden death were apparently the result of myocardial failure.

Trichiniasis had never been known to occur in Greenland, but Thorborg, who was sent to investigate the epidemic, found eosinophilia, positive cutaneous reactions to trichina antigen, positive serologic tests on blood samples and encapsulated trichina larvae in the muscles of a patient who had died of the disease after a three months' illness.

Pork was not involved in this initial outbreak of trichiniasis, and only a few of the patients had eaten dog meat within a month of the onset of symptoms. The only common factor was the synchronization of the epidemic with the walrus-hunting season.

possible contributions to treatment and to constructive mental health that can be made by family physicians, social workers and psychologists and by the church, industry, community organizations and the Government. The final chapter presents a summary and prospect the individual and society. The objective of the book has been to show that mental and emotional ill health is a reaction of personality to the multiple stresses of the total environment, whether the stresses be in external environment, or in the patient's own complicated emotional imbalances. The authors state that mental health cannot be developed in a social vacuum and that to promote positive mental health will require the co-operation and help of many individuals and groups. The material is well organized, and the text is well written. A list of references is appended to each chapter. A good index concludes the volume. The publishing is excellent in every way. The printing is well done with a good large type on good nonglare paper. It is a pleasure to read the book. The book is recommended for all medical, social, public-health and general libraries and to all persons interested in the subject.

*Psychobiology and Psychiatry. A textbook of normal and abnormal human behavior.* By Wendell Muncie, M.D., practicing psychiatrist, chairman, Medical Advisory Board, Seton Institute, Baltimore, and associate professor of psychiatry, Johns Hopkins University, and consultant in psychiatry, U S V A. Second edition 8°, cloth, 620 pp., with 70 illustrations. St. Louis: The C V Mosby Company, 1948 \$9 00.

This second edition has been extensively edited by the author in the light of his experience gained in private practice since the publication of the first edition in 1939. The textbook is based on the teaching of psychiatry at Johns Hopkins University School of Medicine. The historical appendixes of the first edition have been omitted from this edition. A list of selected references is appended to each chapter. A good index concludes the volume. The publishing is well done. The work should be in all collections on psychiatry.

*Encyclopedia of Medical Sources.* By Emerson C Kelly, M.D., associate professor of surgery, Albany Medical College, and attending surgeon, Albany Hospital 8°, cloth, 476 pp. Baltimore: The Williams and Wilkins Company, 1948 \$7 50.

This book is essentially a medical biographic dictionary, in which the fundamental contributions of the persons listed are emphasized, and extensive biographic data omitted. Birth and death dates and domicile are given. Dr. Kelly contributed about 95 per cent of the original publications, a very large coverage, in the interest of accuracy. The names are listed alphabetically, and a comprehensive subject index concludes the volume. The index refers to names and not pages throughout the text. The book is recommended as an essential reference work for all medical and general libraries and to all medical historians.

*Clinical Diagnosis by Laboratory Methods. A working manual of clinical pathology.* By James C Todd, Ph.D., M.D., and Arthur H Sanford, A.M., M.D., professor of clinical pathology, Mayo Foundation, University of Minnesota, and senior consultant, Division of Clinical Laboratories, The Mayo Clinic. With the collaboration of George G Stilwell, M.D., Division of Clinical Laboratories, The Mayo Clinic. Eleventh edition 8°, cloth, 954 pp., with 397 illustrations. Philadelphia: W B Saunders Company, 1948 \$7 50.

This standard popular textbook was published first in 1908 and has gone through ten previous editions, the tenth being issued in 1943. The text of this eleventh edition has been completely revised, and some rearrangement has been made in the subjects. The former chapter on serodiagnostic methods has been divided into three short chapters, and the serodiagnostic tests for syphilis have been included in the second of these chapters. The material on medical mycology has been expanded into a new chapter. The illustrations have been carefully reviewed and rearranged, and new ones added, including new color plates on the blood. A list of references is appended to each chapter. A comprehensive index concludes the volume. The publishing is well done in the characteristic Saunders style. The book is recommended for all medical libraries and to the general practitioner.

*Introduction to Human Physiology.* By William D Zoethout, Ph.D. 8°, cloth, 424 pp., with 138 illustrations and 4 color plates. St. Louis: The C V Mosby Company, 1948 \$4 00.

This elementary manual is well written in a simple, lucid style, and the material is well organized. The type, printing and paper are excellent. The manual should prove of value to students and to all persons interested in the subject. It is recommended for public libraries, where it should prove useful in semipopular collections.

*Clinical Studies in Psychopathology. A contribution to the etiology of neurotic illness.* By Henry V Dicks, M.A., M.D. (Cantab.), F.R.C.P. (Lond.), Nuffield Professor of Psychiatry in the University of Leeds. Second edition 8°, cloth, 238 pp. Baltimore: The Williams and Wilkins Company, 1947 \$4 50.

The author has not made any major changes in this second edition of his small book on psychopathology, but has confined himself to making certain minor improvements. The case records remain the same as in the first edition. The author believes that psychopathology was not changed fundamentally by World War II and therefore has not felt compelled to change his point of view on the subject. Some of the subjects discussed include anxiety and obsessional states, hysteria, sexual perversions, abnormalities of sexual function and drug addictions. A good index concludes the volume. The composition and printing were done in Great Britain, accounting for the yellowish tinge in the paper. The sheets were bound in the United States. The book is essentially an English publication, reflecting the British viewpoint. The volume should be in all neurologic and psychiatric collections.

*Psychotherapy. Its use and limitations.* By D Rhodes Allison, M.D., M.R.C.P., and R G Gordon, M.D., D.Sc., and F.R.C.P. 12°, cloth, 160 pp. New York: Oxford University Press, 1948 \$3 00 (Oxford Medical Publications).

This semipopular manual has been written for the student, the physician and the intelligent layman. It does not describe the methods of psychotherapy but endeavors to present the subject in a broad way, pointing out to the physician and the family ways to help the patient by maintaining his morale and courage. The material is well organized and covers the field of the psychoneuroses, with chapters on the psychoses, mental deficiency and psychopathic personalities. There are chapters on the relation of rheumatism to mental illness, other psychomatic conditions and the patient's reaction to bodily disease. A good index concludes the volume. The book is well published and should prove useful to persons interested in the subject.

## NOTICES

### ANNOUNCEMENTS

Dr Harrison E Kennard announces the removal of his office to 1180 Beacon Street, Brookline, for the practice of general surgery.

Dr Aaron Thurman announces the removal of his office to the Lister Building, 475 Commonwealth Avenue, Boston.

### AMERICAN COLLEGE OF SURGEONS

As previously announced, the twenty-seventh annual Hospital Standardization Conference will be held at the Biltmore Hotel, Los Angeles, from October 18 to 22, in conjunction with the thirty-fourth annual Clinical Congress of the American College of Surgeons.

The opening session of the Clinical Congress is a joint meeting for surgeons and hospital representatives on Monday morning, October 18, at 10 o'clock, at which the president of the American College of Surgeons, Dr Arthur W Allen, of Boston, president-elect of the Massachusetts Medical Society, will preside and speak on "Looking Forward with Hospital Standardization."

Meningitis, other forms, was reported from Boston, 2, total, 2

Meningitis, undetermined, was reported from Arlington, 1, Cambridge, 1, Leominster, 2, Springfield, 1, Westfield, 1, total, 6

Polymyositis was reported from Boston, 2, Cambridge, 1, Dartmouth, 1, Great Barrington, 1, Natick, 1, Waltham, 1, Westford, 1, Worcester, 1, total, 9

Salmonellosis was reported from Medford, 1, Worcester, 1, total, 2

Septic sore throat was reported from Medford, 1, total, 1

Trichinosis was reported from Boston, 1, Cambridge, 1, Lexington, 1, total, 3

Typhoid fever was reported from Chelmsford, 1, Dartmouth, 1, Gloucester, 1, Melrose, 1, total, 4

Undulant fever was reported from Boston, 1, Cambridge, 1, Chesterfield, 1, Dudley, 1, Webster, 1, total, 5

## MISCELLANY

### NATIONAL HEART INSTITUTE

Establishment of the National Heart Institute as one of the National Institutes of Health in the United States Public Health Service has been announced by Oscar R. Ewing, federal security administrator.

Concurrently, Surgeon General Leonard A. Scheele, United States Public Health Service, has announced the appointment of Dr. Cassius J. Van Slyke as director of the National Heart Institute, under the general supervision of Assistant Surgeon R. E. Dyer, director of the National Institutes of Health. In addition, Dr. Van Slyke will be directly responsible to the Surgeon General for co-ordination of all heart-disease activities in the Public Health Service, representing the Service in maintaining relations with professional societies, voluntary agencies and other civic groups that are interested in the progress of the heart-disease program.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Factors Regulating Blood Pressure. Transactions of the first conference, April 24-25, 1947, New York.* Edited by B. W. Zweifach and Ephraim Shorr, Department of Medicine, Cornell University Medical College, New York. New York: Josiah Macy, Jr., Foundation, 1947. \$1.90.

This new conference in the Josiah Macy, Jr., Foundation series of conferences was participated in by nineteen authorities from Boston, New York City and other parts of the country. The papers and discussions deal with the various aspects of the subject. The publication should be in all medical libraries.

*Treatment in General Practice.* By Harry Beckman, M.D., professor of pharmacology, Marquette University School of Medicine, Milwaukee. Sixth edition. 8°, cloth, 1129 pp. Philadelphia: W. B. Saunders Company, 1948. \$11.50.

Dr. Beckman has revised thoroughly this last edition of his standard work on treatment. Many subjects have been completely rewritten, and much material has been added, including balantidiasis, coccidiosis, Colorado tick fever, creeping eruption, geotrichosis, Listerellosis, Loeffler's syndrome, melioidosis, mite infestation, moniliasis, new anemias, non-meningococcal meningitides, North Queensland tick typhus, pulmonary aspergillosis, Reiter's syndrome, rickettsialpox, thrombosis and embolism and the management of penicillin reactions. A long bibliography of sixty-five pages is appended to the text, and a comprehensive index concludes the volume. The text is well printed with a good type, on good light paper. The work is recommended for all medical libraries and for the collections of practicing physicians.

*La penicillina in chirurgia per infiltrazione locale massi a Br. Sante Ciancarelli, chirurgo degli Ospedali di Roma—clin. mal. infettive (Dir. G. Caronia) 4°, paper, 47 pp. Roma: Luigi Pozzi, 1948.*

The author of this small monograph has used his method of local massive infiltration of penicillin in surgical conditions for three years with good results. He describes his method of administration and the dosage used. He has treated osteomyelitis, suppuration of the hand, empyema of the pleura, lung abscess, mastitis, tonsillitis, lymphadenitis, abscesses, peritonitis, cerebral abscess and Ludwig's angina. The text is in Italian. The pamphlet is well printed, with a good type on good paper.

*Conference on Liver Injury. Transactions of the fifth meeting, September 26-27, 1946, New York.* 8°, paper, 128 pp. \$2.25. *Liver Injury. Transactions of the sixth conference, May 1 and 2, 1947, New York.* 8°, paper, 74 pp. \$2.00. Edited by F. W. Hoffbauer, M.D., Mayo Foundation, Rochester, Minn. New York: Josiah Macy, Jr., Foundation, 1947.

The fifth conference on liver injury discussed the relation of dietary factors to chemical liver injury, hepatic functional impairment from vitamin deficiency, liver function, chronic hepatitis and therapy in liver diseases, the sixth considered cirrhosis, the hepatorenal syndrome, chromatography in the study of liver disease and massive hepatic necrosis. These two volumes and the set should be in all medical libraries.

*Diseases of the Skin.* By Oliver S. Ormsby, M.D., attending dermatologist to the Presbyterian Hospital of Chicago, and Hamilton Montgomery, M.D., M.S., associate professor of dermatology and syphilology, Mayo Foundation for Medical Education and Research, Graduate School, University of Minnesota, Rochester. Seventh edition, thoroughly revised. 8°, cloth, 1462 pp., with 683 figures and 11 plates. Philadelphia: Lea & Febiger, 1948. \$18.00.

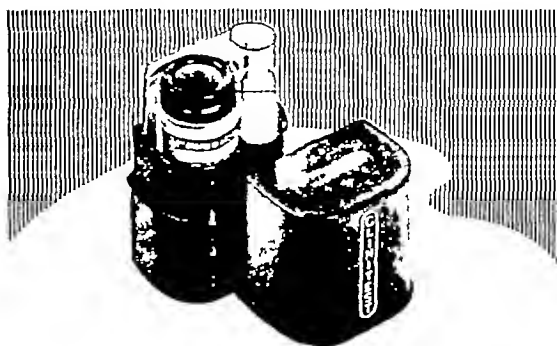

This standard authoritative text has been thoroughly revised by the incorporation of new material and the deletion of obsolete material. The additions include a number of new diseases not described in the previous edition and new methods of treatment of syphilis and other diseases with penicillin and other antibiotics. To keep the volume within bounds some chapters have been condensed and some of the text printed in small type. Ninety figures and eleven color illustrations have been added to the text. References have been limited and printed as footnotes on the appropriate pages. A good index concludes the volume. The book is well published and is recommended for all medical libraries and to dermatologists and physicians interested in diseases of the skin.

*Mental Health in Modern Society.* By Thomas A. C. Rennie, M.D., associate professor of psychiatry, Cornell University Medical College, and director, Division on Rehabilitation, National Committee for Mental Hygiene, and Luther E. Woodward, Ph.D., field consultant, Division on Rehabilitation, National Committee for Mental Hygiene. 8°, cloth, 424 pp. New York: The Commonwealth Fund, 1948. \$4.00.

The authors have based their book on actual work in the field of mental health, in psychiatry and psychiatric social work in the New York Hospital Rehabilitation Clinic for Psychiatrically Disabled Veterans and in field work in communities and states and in the sharing of experience with leaders in the various governmental and public services. The work is divided into three parts: lessons from the war period in four chapters, post-emergency problems in mental health, in one chapter, and sources of help in treatment and prevention, in eight chapters. The work is so comprehensive that an analytical review is excluded because of space limitations that will permit only an indication of the contents. The war period is discussed under the headings of mental-health services in the armed forces, emergency measures for aiding veteran-civilian adjustment, and psychiatric disabilities of war dynamics and motivation, principles, methods and results of treatment. The second part considers the continuing mental-health problems and needs, including problems of the wounded and veterans with psychiatric disabilities, the effect of war on the civilian population research and problems relating to more and better treatment of the mentally ill. The third part discusses the

## COLLEGE OF AMERICAN PATHOLOGISTS

The Northeastern Regional Meeting of the College of American Pathologists will be held at the Massachusetts General Hospital, Boston, on September 18

## PROGRAM

- 8 30-9 30 a m Registration  
 9 30-10 00 a m Recent Advances in Laboratory Diagnosis of Pregnancy Stanley L Robbins, M D  
 10 00-10 30 a m Hormonal Alteration of Breast Carcinoma Ira T Nathanson, M D  
 10 30-11 00 a m Practical Problems in the Rh Investigation Louis K Diamond, M D  
 11 00-11 30 a m Neuropathology Its current methods and values Raymond D Adams, M D  
 11 30 a m-12 00 m The Use of Photoelectric Spectrophotometry in Clinical Problems Francis T Hunter, M D  
 12 00 m-12 30 p m The Role of the Laboratory in the Diagnosis of Tuberculosis William Steenken, Jr, M D  
 12 30-2 00 p m Luncheon in Cafeteria, Massachusetts General Hospital  
 2 00-2 30 p m Diagnostic Procedures in Virus Diseases of the Respiratory Tract Maxwell Finland, M D  
 2 30-3 00 p m Diagnostic Procedures in Certain Virus Diseases of the Central Nervous System John F Enders, M D  
 3 00-4 00 p m Pathology of the Newborn Sidney Farber, M D  
 4 00-5 00 p m Difficulties and Pitfalls in Interpretation of Vaginal and Pulmonary Smears by the Papanicolaou Method Ruth M Graham, S B  
 6 00 p m Fellowship  
 7 00 p m Dinner at Hampshire House, 84 Beacon Street, Boston (\$4.60 per person)  
 8 00 p m Human Sexuality John Roek, M D

## AMERICAN TRUDEAU SOCIETY

The Eastern Section of the American Trudeau Society will meet on October 15, 1948 at the Rutland State Sanatorium, Rutland, Massachusetts. This meeting will be among the events arranged to mark the fiftieth anniversary of the opening of the institution, the first of its kind in America.

## METROPOLITAN STATE HOSPITAL

The Fourteenth Postgraduate Seminar in Neurology and Psychiatry will begin on Friday, October 1. The program will be as follows: a review course in basic neurology and psychiatry, consisting of sixty-six lectures to be held every Friday from 2 to 10 p m from October 1 to December 3, 1948, and from March 4 to May 20, 1949, at the Metropolitan State Hospital, 475 Trapelo Road, Waltham, a course in social and special psychiatry consisting of thirty-six lectures, to be held every Wednesday from 5 30 to 10 p m from October 13 to December 8, 1948, and from March 16 to May 11, 1949, at the Boston Psychopathic Hospital, 74 Fenwood Road, Boston, and a course in pediatric neuropsychiatry (child psychiatry) consisting of twenty lectures, to be held every alternate Monday from 6 to 10 p m from October 11 to December 6, 1948, and from March 14 to May 9, 1949, at the Walter E Fernald State School, Waverley.

All interested graduate physicians should apply before October 1 in writing to Dr William C Gæbler, superintendent, Metropolitan State Hospital, Waltham.

The applicants should indicate which of the three courses of the Seminar they wish to attend. The registration is requested as a matter of courtesy to the institutions where courses are conducted and as a convenience for the registrants, who will thus be able to receive the schedules and who will be notified in time in case changes in the schedule should become necessary during the year.

## AMERICAN SOCIETY OF ANESTHESIOLOGISTS

The annual meeting of the American Society of Anesthesiologists will be held in St. Louis from November 4 to 6.

## THE FOUNDATION PRIZE

The South Atlantic Association of Obstetricians and Gynecologists announces the establishment of the Foundation Prize. Authors of papers on obstetric or gynecologic subjects desiring to compete for the prize may obtain information from Dr E D Colvin, secretary-treasurer, 1259 Clifton Road, N E, Atlanta, Georgia.

## COLORADO STATE MEDICAL SOCIETY

The annual meeting of the Colorado State Medical Society will be held in Glenwood Springs from September 22 to 25 (secretary, H T Sethman, Republic Building, Denver 2, Colorado).

## INDIANA STATE MEDICAL ASSOCIATION

The annual meeting of the Indiana State Medical Association will be held in Indianapolis from October 26 to 28 (secretary, Ray E Smith, 23 East Ohio Street, Indianapolis 4, Indiana).

## KENTUCKY STATE MEDICAL ASSOCIATION

The annual meeting of the Kentucky State Medical Association will be held in Covington from September 27 to 30 (secretary, P E Blackerby, M D, 620 South Third Street, Louisville 2, Kentucky).

## MICHIGAN STATE MEDICAL SOCIETY

The annual meeting of the Michigan State Medical Society will be held in Detroit, September 22 to 24 (secretary, L Fernald Foster, M D, 2020 Olds Tower, Lansing 8, Michigan).

## NEVADA STATE MEDICAL ASSOCIATION

The annual meeting of the Nevada State Medical Association will be held in Ely on September 24 and 25 (secretary, Roland W Stahr, M D, 118 California Avenue, Reno, Nevada).

## MEDICAL SOCIETY OF VIRGINIA

The annual meeting of the Medical Society of Virginia will be held in Richmond from October 18 to 20 (secretary, Miss A V Edwards, 1200 East Clay Street, Richmond 19, Virginia).

## WASHINGTON STATE MEDICAL ASSOCIATION

The annual meeting of the Washington State Medical Association will be held in Seattle from October 3 to 6 (secretary, John P McVay, M D, 327 Cobb Building, Seattle 1, Washington).

## STATE MEDICAL SOCIETY OF WISCONSIN

The annual meeting of the State Medical Society of Wisconsin will be held in Milwaukee from October 4 to 6 (secretary, C H Crownhart, 110 East Main Street, Madison 3, Wisconsin).

## SOCIETY MEETINGS AND CONFERENCES

## EPIDEMIOLOGY IN COUNTRY PRACTICE\*

WILLIAM N. PICKLES, M.D.†

AISGARTH, YORKSHIRE, ENGLAND

AS I studied the long list of my illustrious predecessors who have presented the Cutter Lecture on Preventive Medicine I was truly grateful to the pious founder, that modest and yet forceful character, Dr. John Clarence Cutter, for the opportunity to visit this great country, to receive so many kindnesses from so many people and to find a truly New World opened to us on this side of the Atlantic. But what had I to offer in comparison with such eminent men? For I come to speak about very simple things, everyday happenings and elementary deductions drawn from them such as are within the scope of but a meager intellectual equipment. Yet I feel, as William Budd felt a hundred years ago, that country districts have certain advantages for the study of epidemiologic problems and that the ability of the observer is of secondary importance to his opportunities, which indeed are great. It is always my delight to quote this pioneer, whose conclusions were assailed with fierce criticism in his lifetime and who was completely forgotten until a very few years ago. I shall let him speak for himself.

It is obvious that the formation of just opinions on the question how diseases spread may depend less on personal ability than on the opportunities for its determination which may fall to the lot of the observer.

It is equally obvious that where the question at issue is that of the propagation of diseases by human intercourse, rural districts, where the population is thin and the lines of intercourse are few and easily traced, offer opportunities for its settlement which are not met with in the crowded haunts of large towns.

William Budd began his career with a term of country practice in his native village in Devonshire, where he made his memorable observations on typhoid fever.

The other pioneer whom I should like to quote is Peter Ludwig Panum, the Dane who was sent as a youngster to the Faroe Islands to investigate an epidemic of measles. Although this is also a hundred years ago there is little to add to the knowledge of the epidemiology of measles that he acquired. He wrote similarly to Budd the

isolated situation of the villages and their limited intercourse with each other made it possible in most cases to ascertain where and when the person who fell ill had been exposed to infection and to prove that the contagion could not have affected him either before or after the date stated.

Reminiscences are the privilege of the garrulous old, and I hope I shall be forgiven at this point if I am autobiographical. I recall most vividly the following incident: a gypsy woman driving a caravan into a village in the summer twilight, a sick husband in the caravan, a faulty pump at which she proceeded to wash her dirty linen, and shortly afterward my first and only serious epidemic of typhoid fever, which left me with a lasting impression of the unique advantages of the country doctor for the investigation of infectious disease. This incident showed me the ease with which an epidemic can be traced in the country and the ease with which it can be brought to an end. The handle of the Broad Street pump was removed at the urgent request of John Snow, because he believed that its clear and sparkling water contained the deadly poison of cholera. In this instance of mine, the handle was chained to the pump, where indeed it remains to this day, and there were no more primary sufferers. This was in 1910. I was twenty-five years of age and a very inexperienced assistant in a country practice, very near the one in which I have spent my life. Shortly afterward I had another memorable experience.

Now I have a friend, a very young friend—he is not yet five years of age. He is accomplished. He can play quite pleasingly on the piano. He can read and even write a little. I said to him one day, "John, you'll soon be going to school, you will enjoy that." He replied, "I'm not going to school, I know it all." That is the attitude of many young doctors entering general practice, especially if they have done a number of house jobs, and that, in those far-off days, was my attitude. I knew it all, and I got some shocks. And one of the shocks was the presence of an entirely new infectious disease—jaundice in epidemic form.

## EPIDEMIOLOGY IN COUNTRY PRACTICE\*

WILLIAM N. PICKLES, M.D.†

ALSGARTH, YORKSHIRE, ENGLAND

AS I studied the long list of my illustrious predecessors who have presented the Cutter Lecture on Preventive Medicine I was truly grateful to the pious founder, that modest and yet forceful character, Dr. John Clarence Cutter, for the opportunity to visit this great country, to receive so many kindnesses from so many people and to find a truly New World opened to us on this side of the Atlantic. But what had I to offer in comparison with such eminent men? For I come to speak about very simple things, everyday happenings and elementary deductions drawn from them such as are within the scope of but a meager intellectual equipment. Yet I feel, as William Budd felt a hundred years ago, that country districts have certain advantages for the study of epidemiologic problems and that the ability of the observer is of secondary importance to his opportunities, which indeed are great. It is always my delight to quote this pioneer, whose conclusions were assailed with fierce criticism in his lifetime and who was completely forgotten until a very few years ago. I shall let him speak for himself.

It is obvious that the formation of just opinions on the question how diseases spread may depend less on personal ability than on the opportunities for its determination which may fall to the lot of the observer.

It is equally obvious that where the question at issue is that of the propagation of diseases by human intercourse, rural districts, where the population is thin and the lines of intercourse are few and easily traced, offer opportunities for its settlement which are not met with in the crowded haunts of large towns.

William Budd began his career with a term of country practice in his native village in Devonshire, where he made his memorable observations on typhoid fever.

The other pioneer whom I should like to quote is Peter Ludwig Panum, the Dane who was sent as a youngster to the Faroe Islands to investigate an epidemic of measles. Although this is also a hundred years ago there is little to add to the knowledge of the epidemiology of measles that he acquired. He wrote similarly to Budd the

isolated situation of the villages and their limited intercourse with each other made it possible in most cases to ascertain where and when the person who fell ill had been exposed to infection and to prove that the contagion could not have affected him either before or after the date stated.

Reminiscences are the privilege of the garrulous old, and I hope I shall be forgiven at this point if I am autobiographical. I recall most vividly the following incident: a gypsy woman driving a caravan into a village in the summer twilight, a sick husband in the caravan, a faulty pump at which she proceeded to wash her dirty linen, and shortly afterward my first and only serious epidemic of typhoid fever, which left me with a lasting impression of the unique advantages of the country doctor for the investigation of infectious disease. This incident showed me the ease with which an epidemic can be traced in the country and the ease with which it can be brought to an end. The handle of the Broad Street pump was removed at the urgent request of John Snow, because he believed that its clear and sparkling water contained the deadly poison of cholera. In this instance of mine, the handle was chained to the pump, where indeed it remains to this day, and there were no more primary sufferers. This was in 1910. I was twenty-five years of age and a very inexperienced assistant in a country practice, very near the one in which I have spent my life. Shortly afterward I had another memorable experience.

Now I have a friend, a very young friend—he is not yet five years of age. He is accomplished. He can play quite pleasingly on the piano. He can read and even write a little. I said to him one day, "John, you'll soon be going to school, you will enjoy that." He replied, "I'm not going to school, I know it all." That is the attitude of many young doctors entering general practice, especially if they have done a number of house jobs, and that, in those far-off days, was my attitude. I knew it all, and I got some shocks. And one of the shocks was the presence of an entirely new infectious disease—jaundice in epidemic form.

## EPIDEMIC HEPATITIS

My elderly principal, having been born, brought up and having practiced in the neighborhood, had seen several similar epidemics of jaundice. They were familiar experiences to him, and he laughed at my perplexity. However, reference to my textbooks somewhat restored my self-esteem for the writers seemed to be, and actually were, in precisely the same state of abysmal ignorance as I was myself, and only touched on a very serious form of infectious jaundice, which they called "Weil's

form of jaundice upon which a quack doctor could thrive, I suppose even he would be baffled by sufferers from stone in the common duct or cancer of the head of the pancreas. He was only doing what so many of us do — keeping his patient in a state of tranquillity while nature effected the cure. That there actually was a man who acquired this title presupposes a large number of sufferers and that most certainly of epidemic hepatitis. His remedy, by the way, was a decoction of barberry bark or the bark of the common berberis, which grows wild in the district, most likely an escape

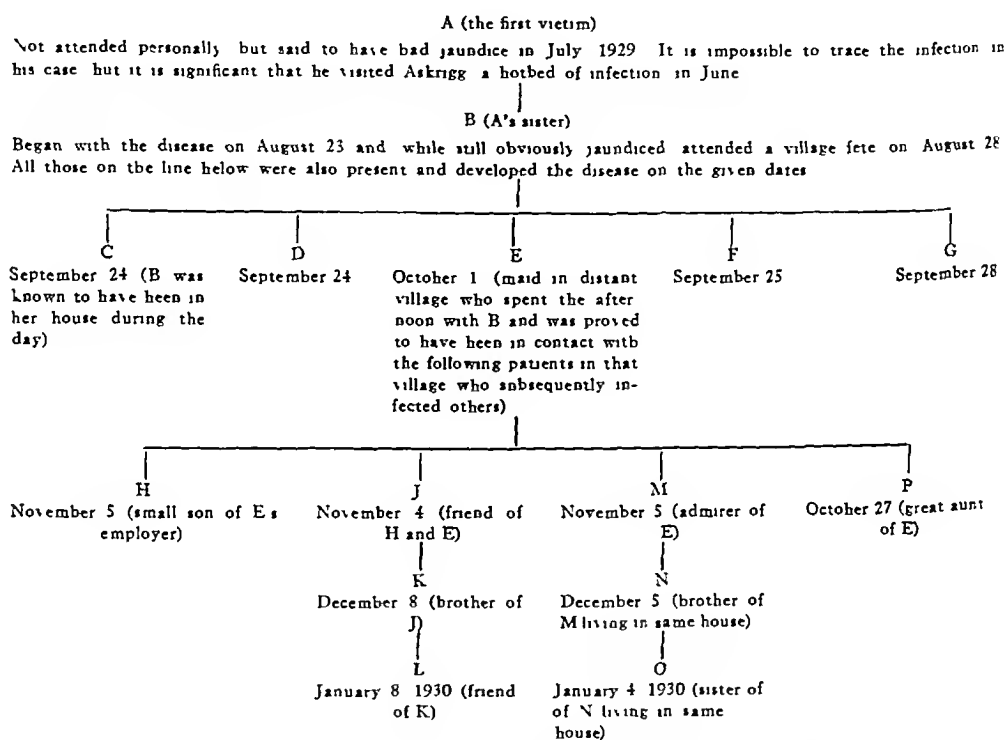

FIGURE 1 Course of Epidemic Hepatitis among Villagers Who Attended a Fete

disease", I pondered long and often whether this could be the same disease as that I was faced with. Others have pondered in the same way. It is a strange thought that the same agent that produced these epidemics so prevalent in country districts, and more interesting than serious, should in the late war have assumed such importance. That these epidemics have been for long prevalent in country districts is to my mind clear. So far as my own district is concerned, I have the evidence of my old principal, — no mean practitioner of his art, — the tradition of the countryside and the knowledge that seventy years ago there lived in Wensleydale a jaundice doctor who combined this useful occupation with that of a castrator.

Epidemic hepatitis as I have seen it — generally speaking requiring no treatment — is just the

from some ancient herb garden. After 1910 I never saw epidemic jaundice until 1929, and then I saw it to some tune. In a population of 5700 there were at least 250 sufferers, and of these I myself attended 115. I do not intend to enter the clinical field beyond stating that the disease ran a mild course in the great majority of my patients. It is on the epidemiology that I wish to concentrate.

Now, those busybodies the pathologists — or that branch of them which deals with and, of course, knows all about the virus — have gravely prejudiced the issue by discovering the virus of hepatitis in the stools of sufferers from this disease and have to such an extent captured the imagination of observers that it is almost assumed that infection must be by this means and no other. He would be a bold man who now asserted that the infection

could not be by the feces, but I do not want to stress that, in this and all succeeding epidemics that I have encountered, I felt justified in attributing the spread to personal contact, most likely by droplet infection. Contact sufficient to reproduce the disease was often casual, and there were no explosive outbreaks such as would have occurred from the contamination of food and water. Just the same thing has happened in poliomyelitis, and although I have not seen any reference to the discovery of virus A or B of influenza in feces — except in those of inoculated mice — I think that their presence is highly probable in this disease, and yet we shall most of us still go on believing that influenza is spread from person to person by droplet infection.

I am afraid I have repeated very often the story of a village fete depicted in Figure 1, but it gives evidence of the incubation period of about a month suggested by Booth and Okell and it is definitely my best example. Looking half way down the story one sees that five people began with the disease within a week, and I discovered that they had one experience in common: they had all been present at a fete in one of our villages on August 28. Some sufferers from the disease had therefore probably been present at the fete. After prolonged search I found that a young girl who had begun with the disease on August 23 had been at the entertainment. I had actually seen her in bed in the morning and never dreamt she could have left it. She must have eluded me with great skill throughout the afternoon, since I was there myself and never set eyes on her. She spent the afternoon with E, another young girl, and was in the house of Mrs. C, so that I think it is a fair presumption that she infected them and the other three. This young girl E, a maid in another village, infected four others. One was her employer's small son, another his friend, and another her own great-aunt. All this was reasonably clear. Of the fourth — M — there was some doubt. He was a rather pathetic little fellow of forty (since dead of a tuberculous kidney) and denied all acquaintance with this young girl. However, his sister gave him away shamelessly. "Robert not know Margaret?" said she, "Why he's very fond of her — he generally goes in at the back door in the evenings and helps her to wash up." Robert might well have said with Samson, "If ye had not plowed with my heifer, ye had not found out my riddle." A brother of Robert succumbed a month later, and in January, with poetic justice, the tell-tale sister. Thus, to my knowledge, one young girl determined to have what she considered her legitimate amusement, jaundice or no jaundice, and was responsible for 13 sufferers.

Figure 2 thus shows an epidemic in a family of young adults and among their friends. It shows rather clearly the monthly incubation period and suggests a short period of infectivity. I do not

think one could explain this serial incidence without this assumption. I have acted on this assumption and allowed children, if they were well enough, to resume school after the fourteenth day, — well on the safe side, — with no evidence of spread of the disease. I came to the conclusion in 1930 that the incubation was about a month, the infectivity period about a week and the disease was spread by personal contact, probably by droplet infection, and I have nothing to add to these conclusions,

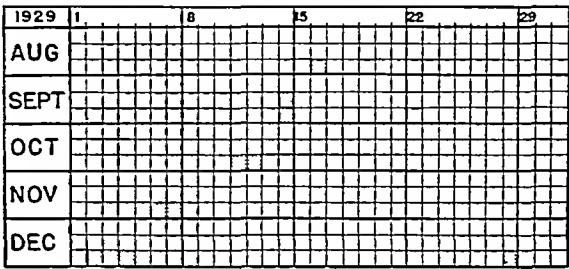

FIGURE 2 Epidemic Hepatitis

since I have been fortunate enough to observe seven further — if smaller — epidemics, which have all faithfully reproduced these features.

EPIDEMIOLOGIC METHOD

Let us return for a few moments to the peculiar opportunities of the country doctor. I recall a particularly lovely evening in early summer when I climbed alone to the top of one of our noble hills. The setting sun lit up the grim pile of an ancient castle, once the prison of that unhappy queen, Mary of Scotland. Our attractive little lake seemed to lie at my feet, and one by one I made out most of our gray villages with their pall of smoke. And as I watched the evening train creeping up the valley, with its pauses at our three stations, I had this strange thought, that there was hardly a man, woman or child in all those villages of whom I did not know even the Christian name and with whom I was not on terms of friendship. My wife and I say we know nearly all the dogs and indeed many of the cats. Now, does not this intimate knowledge of his flock put the country doctor in a superior strategic position for the study of such a subject as epidemic disease? I could say much of my patients, the Yorkshire dalesfolk, of their shrewdness and ability, of their remarkable memories, of their startling intelligence, which tempts me to deplore that in some ways education blunts the edge of intelligence, of that seemingly impenetrable crust, which is only a crust, concealing great friendliness and goodness of heart. These are just the people to help a doctor in his investigations. Matters so delicate as heredity and consanguinity have to be

approached with care, but on the whole I have found my patients co-operative and slow to take offense. Also, I cannot help knowing much about the details of their relatively simple existence. I have known the grandparents of many of my present-day patients and have been able to trace characteristics, medical and otherwise, through the generations to the present day. Today I know what markets the farmers frequent, the schools their children attend, the young people's love affairs, the festivities that take place at intervals in every

retire with reluctance, knowing that our real life is then over and fearing to experience that utter loneliness which comes from a separation from our work and from our friends. Not everyone has the temperament of a Diocletian — content to throw aside the purple and grow cabbages, and, as good students of Gibbon will remember, even he lived to regret it.

You have, of course, in the United States the very best example of continuity in a practice. In 1872 George Huntington described examples of

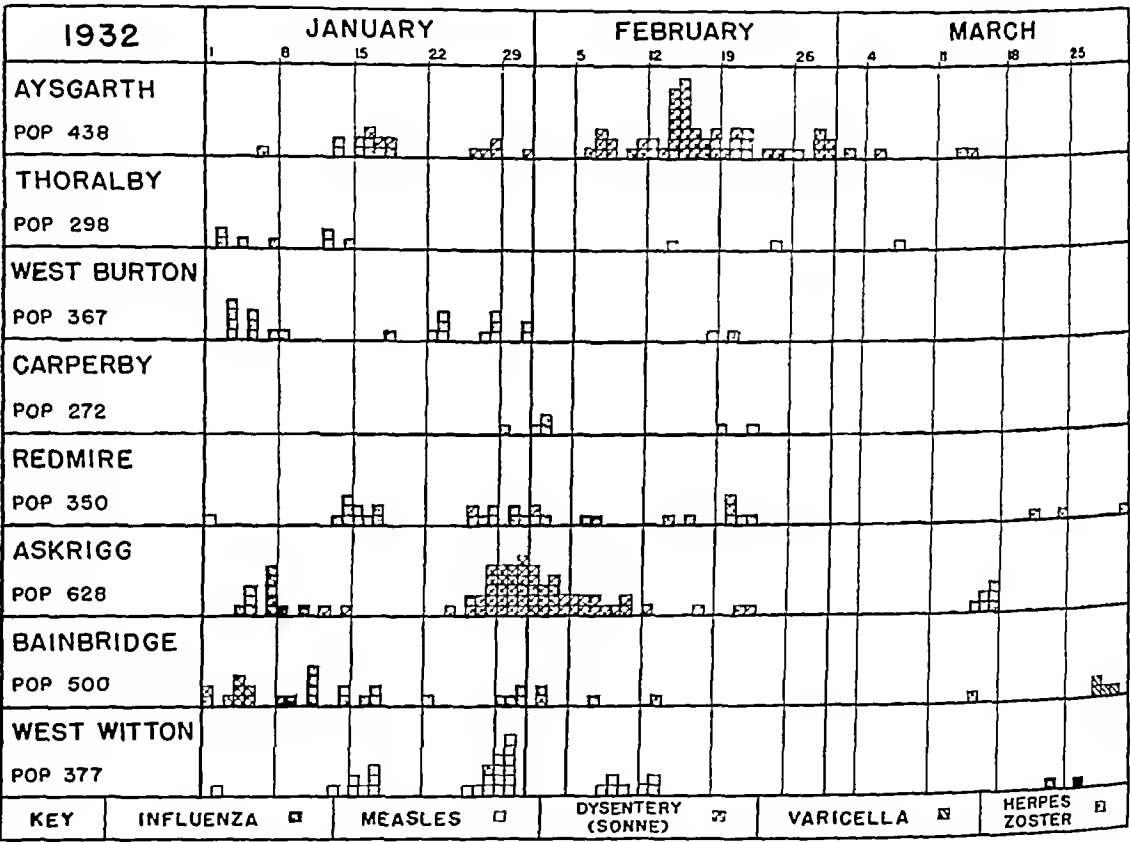

FIGURE 3 Example of Village Epidemiologic Records (in the Actual Charts the Key Squares Are in Various Colors)

village of the dale, the visits to the large towns for shopping or the yearly expedition to the Pantomime and the summer trip to the seaside. On many of these expeditions, infectious disease has been introduced into our midst, and one is rarely in doubt about the origin of any epidemic. A little help and encouragement turns the schoolmaster into an enthusiastic epidemiologist, and I have been fortunate all these years in having an ally, the headmaster of the grammar school, which serves a large area and is often responsible for the spread of epidemics. There is, moreover, stability and continuity of country practice. Most of us show but little inclination to change our habitat and

the chorea that bears his name, and it was a fact that his father, grandfather and great-grandfather had traced these sufferers through the generations and found among other things that the disease did not skip a generation.

Now a few words on technic. If one sets about to study epidemics in country practice one must have some simple technic. I carry a pocket diary, and at the bedside each sufferer is entered in the diary under the date on which the disease began — for example, March 10, 1947, Jonathan Metcalfe, aged ten, village of Aysgarth, measles and so forth. At suitable intervals these are entered on the charts (Fig 3).

A chart is kept of every quarter as it comes along. The names of the villages are arranged in what I consider their natural groups, the whole on graph paper. A colored square is decided on for each infectious disease, and each patient is allotted a square placed opposite the appropriate group of villages and beneath the date on which the disease began. These charts are bound in book form. The names and ages of the sufferers are written on the opposite side of the page under the particular symbol of the disease, with short notes, clinical and epidemiologic, as necessary. It is the short and only possible exposure that one is always on the lookout for, the following examples occurred during an epidemic of measles.

A man in a village remote from the prevailing epidemic exhibited the disease. Twelve days previously a friend of his had called at my surgery and, finding no one at home, had repaired to the inn conveniently situated on the other side of the road, and sat cheek by jowl with this man over their drinks. Returning to the surgery he was found to be suffering from measles. During the short visit to the inn he appeared without a reasonable doubt to have infected his companion, and the incubation period was most accurately twelve days.

A boy employed on a farm arrived at the surgery on his bicycle and announced he had "gotten mazzles" (contracted measles). This certainly was the case, and he was told to go to his mother's house and shout to her the same tidings outside the door, that she might have the living room cleared of his young brothers and sisters. He then remained in his bedroom for a fortnight. On the twelfth day after his arrival, his aunt, and only his aunt, became a victim of the disease although she had never seen the boy and had left the house the morning after his arrival. It was found that the boy's bedroom and the living room directly below, by a usual and capricious arrangement of the builder, were lighted by one long window, giving direct aerial access from one room to another. The meal table was directly below this gap and the aunt, who sat directly underneath at meals, was apparently thus infected.

Mumps pays only occasional visits and in the last large epidemic, in 1935, traversed the district with measured stride, owing to its long incubation period, and lasted a whole year. It was a long time before I had a case of the short and only possible exposure, but it arrived. Betty was a bridesmaid at a wedding outside the district on June 11. She was a rather sick little bridesmaid and was later found to have this disease. On the evening of June 26 her mother first had symptoms and a few days later showed a letter from her sister, the bride of the eleventh, stating that her symptoms had also begun on the same evening. The incubation period in the bride was definitely fifteen days. Later, I had several similar cases and the period was never less

than fifteen days and never longer than seventeen or eighteen.

### INFLUENZA

At this point I think we should enter on the subject of influenza, the most important of our epidemic visitants. Influenza, more than any other disease, transforms the busy but orderly existence of the country doctor into a nightmare. To visit fifty houses as I have done in a country district and see three times that number of patients is no small feat in the space of a working day, however long. Some of these have to be visited a second time late at night and there are always visits to our *malades imaginaires*, who dread that they will be neglected in such a strenuous period. In the 1937 influenza epidemic the ferocity lasted under a month as it spread quickly from village to village, owing, I believe, to the improved methods of transport.

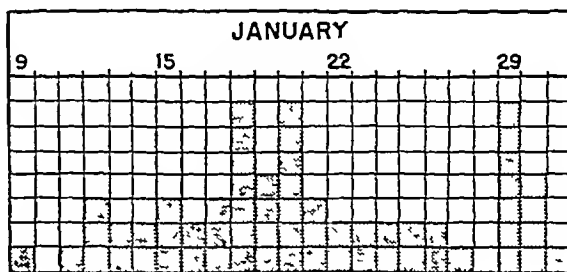

FIGURE 4 Influenza.

Lately, it has been the policy of the education authorities to close the small schools and concentrate on those in the larger villages. This may be good in the cause of education, but it adds substantially to the spread of infection. It gives us visits to isolated farms that might otherwise have escaped and many walks in the midst of strenuous days over sodden fields, not at all acceptable.

Figure 4 shows part of an epidemic in 1935. A schoolmistress returning from a Christmas visit to her parents in Scarborough, feeling far from well, attended her school on the first day of opening. She attended a brief morning session and then was quite unable to continue. In this session she was responsible for 78 victims among her charges and their families. I was not aware of this until I studied my charts later, and the worthy lady is probably not aware of it to this day. It is quite definite that this village, which was the only one to suffer severely in 1935, almost escaped in 1937, suggesting some measure of immunity in a village population. In 1946 I had the privilege and pleasure of a visit from that great Australian scientist, Professor Frank Burnet. He agreed with me on this point, and later we were able to prove from my charts that in a

village community there was a considerable degree of immunity to influenza for four years but that this declined and faded altogether in seven I think the help I got from Burnet on this occasion illustrates what I have often said that it is the role of the country doctor to collect facts from which others more skilled can draw conclusions

Influenza appeared in Wensleydale in 1943, imported by a schoolmistress who had spent the half-

the only occasion in which I have attended the same patient with this disease twice

On May 6, 1937, a young married woman developed shingles, and on the following day, a young farmer in a village four miles distant. They had an experience in common, having attended a sale in the latter's village a fortnight before and having tea at the farmer's house, his wife being a great friend of the young married woman. Infection for both appears to have been acquired at one or other of these entertainments, although in this case I was unable to trace the culprit. The male sufferer was present on the day of national rejoicing, May 12, the Coronation of King George VI, at the local junketings, which took the form of the usual tea and sport, and his victims are shown in Figure 6. The grandfather of one of these later developed shingles. I take it that the close connection between the two diseases is now firmly established, but it has been interesting on many occasions to find cases of this association, if only to show the advantages of country practice.

In the months June to October, 1940, we also had the two diseases and during the same period five sufferers from Bell's palsy. Bell's palsy has been a very rare disease to me. Actually, in thirty years of practice I had never seen a single case, and naturally 5 sufferers in a short period set me thinking. The presence of shingles and chicken pox was significant, although there appeared to be no direct connection between them and the sufferers from facial paralysis. Professor J. F.

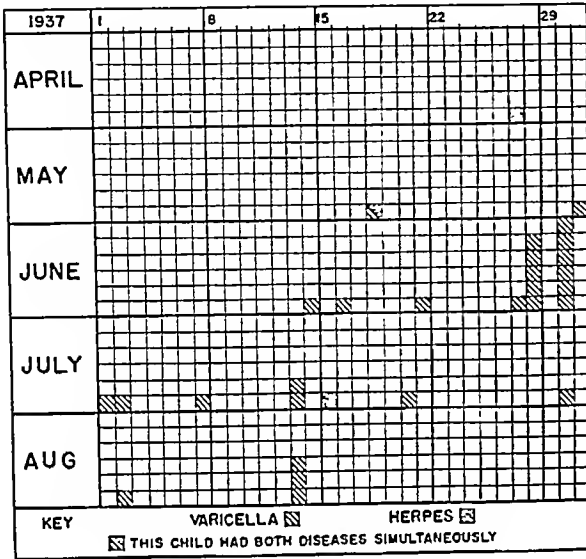

FIGURE 5 Chicken Pox and Shingles I

term holiday in Manchester. I saw several girls in this school suddenly stricken with what was undoubtedly clinical influenza in the first week of November when there was no sign of the presence of an epidemic in the country at large according to the weekly records of influenza deaths. By the end of the year these had risen to 1300 per week.

#### CHICKEN POX AND SHINGLES

On April 27, 1937, a young married woman exhibited the initial symptoms of supraorbital herpes. On May 18 her baby daughter developed herpes zoster in the lumbar region and widespread chicken pox, a fairly rare combination (Fig 5). On May 31, a little girl much attached to the baby next developed the disease, but returning to school one week after falling ill, I believe, also infected this one, explaining why the entry comes out of its turn. The epidemic spread to the sister village and claimed another victim from herpes zoster. This patient lived at a farm really in the wilds, and the only possible infector was a small girl who was taken there by her mother three days before she developed a rash, suggesting that she was infectious at the time. This child also added to one's knowledge later, in that she again developed chicken pox in 1945,

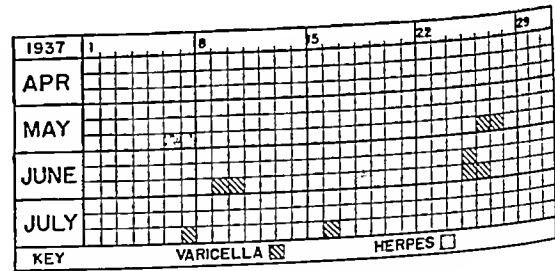

FIGURE 6 Chicken Pox and Shingles II

Bedson, of the London Hospital, most kindly undertook complement-fixation tests on the serum of three of these, but only one was positive for the virus of herpes and varicella. Thinking about this afterward, I do not consider that one would have got valuable information from these tests, except for negative reactions, for most people have had one or other disease and would presumably give positive serum results. One of the negative reactors gave us far more information by developing a most severe attack of chicken pox within the year showing I believe, conclusively that the facial paralysis was not due to the virus. I am inclined to

believe that these sufferers were infected by some virus allied to poliomyelitis of which they were the only efflorescent examples. Later I did have a patient suffering from facial paralysis who had unmistakable herpes vesicles in his auditory meatus. In the autumn of 1947, when we also had our first experience of a poliomyelitis epidemic, one little boy developed facial paralysis with no further extension. All these patients completely recovered.

#### FREQUENCY OF INFECTIOUS DISEASE

That the charting of epidemic disease in country practice is a formidable task may be gathered from the fact that in fifteen years and three months, 4855 cases of infectious disease have been recorded (Table 1). Influenza tops the list, followed by the diarrheal diseases—often Sonne dysentery. At the bottom, thank God, comes diphtheria.

It was recently pointed out by a colleague to whom I was showing this list that perhaps teaching bodies did not realize how few of these diseases, which loom large in a general practitioner's work, are even seen by the student in his ordinary course. This seems to suggest that facilities should be given him to visit patients in their own homes so that he does not see sufferers from these diseases for the first time when he takes up practice on his own account. Furthermore, I believe from the human point of view it would be a corrective to hospital outpatients—that varied collection of interesting cases—for a student to go alone into a patient's house and find out that his life is to be spent attending to men, women and children—not cases—and also to see at first hand under what conditions they live.

#### ERYTHEMA NODOSUM

Erythema nodosum is not a common disease in any experience and many years ago I began charting sufferers, thinking the complaint had many points in common with the exanthemas. Now the record is there so that I can follow up the connection with tuberculosis. To my sorrow in 1 case in the spring of 1946, the connection was only too obvious. A little girl of eight—the idol of her family—having just recovered from this disease died within two days from tuberculous meningitis.

#### PREVENTION OF DIPHTHERIA

I think I should say a little about diphtheria prophylaxis. In my time in Wensleydale diphtheria has rarely appeared, but when it comes it kills, and consequently protective inoculation has now for many years been an especial care. Bearing in mind that in inoculated children added protection is acquired by subsequent actual experience of the organism, I had a little doubt whether it was possible to produce permanent immunity in a child population in which this experience was largely lacking. Dudley showed in his inoculated boys at

Greenwich Hospital School that there was a temporary rise in the carrier rate, but in Hamilton, Ontario, after many years of a high percentage of inoculations, carriers virtually disappeared suggesting that the germ had been banished from the city. That is all to the good if one remains in Hamilton, but if one becomes a Canadian soldier and is drafted to a camp in England, it is possible that one's immunity may be low and if exposed to diphtheria,

TABLE 1 *Cases of Epidemic Disease*

DISEASE	NO OF CASES
Influenza	1112
Diarrhea and vomiting	1018
Measles	510
Febrile catarrh	407
Chicken pox	318
Whooping cough	295
Tonsillitis	289
Mumps	235
German measles	175
Herpes zoster	140
Hepatitis	122
Scarlet fever	117
Lobar pneumonia	41
Glandular fever	41
Bornholm disease	25
Diphtheria	12
Total	4855
Erythema nodosum	12

one may develop diphtheria, and that is precisely what did happen.

Bearing all this in mind, it was with some trepidation that I undertook a Schick-testing campaign some years ago. The numbers, I realize, are small, but this would be the experience of anyone undertaking such a campaign in a country practice. I tested in all 306 inoculated children, some two years and some five years after the inoculation. I found 36 reactors—that is, 11.76 per cent. Omitting the control and using only the toxin, reading at the end of the week even slight redness as positive, it is very probable that some pseudo-reactions were included. Therefore, the total of only 36 reactors in these children was not discouraging.

#### BORNHOLM DISEASE

Let me give you a personal experience of a somewhat rare infectious disease. When I have touched so lightly on the common infectious diseases I feel I must quote

Who goes gleaming  
Hedge-side chance blades, while full sheaved  
Stand cornfields by him

To meet with one illness to which formal diagnosis cannot be given is no rare experience, but to be faced with a series of 7 cases of what was apparently an undescribed infectious disease was the lot of my partner, the late Dr. Dean Dunbar, and myself in the summer of 1933. I should like to emphasize the atmosphere of utter helplessness that

prevailed before a diagnosis was forthcoming, believing that a like experience might be the fate of other general practitioners

In the early morning of a bright July day I was roused from my bed by a young farmer, thoroughly alarmed, who asked if I would come to one of his small boys who had been taken seriously ill. This boy, aged two and a half years, had been quite well and lively while being dressed but then was suddenly attacked with pain in the upper part of the abdomen, sweated profusely and was thought by his mother to have had a fit. When I saw him the pain was not so acute, but he was deadly pale, looked limp and ill, and was taking short shallow breaths, which were obviously causing him discomfort. At this stage his temperature was 98°F. Later in the morning my partner saw him with a return of the acute pain and suggested that there was a painful spasm of the respiratory muscles, probably of the diaphragm — a very acute clinical observation. We saw him together at 3 o'clock, and again the picture was changed. His face was flushed, his temperature was 101°F, and his respirations were definitely 60 to the minute. At this point we felt on firmer ground and believed that we were justified in suggesting to the parents that the child was beginning with acute pneumonia although physical signs of this disease were entirely absent. I still think, and believe you will agree, that this was a reasonable suggestion. In the evening the patient seemed better, to add to our difficulties if at the same time to bring us peace of mind. His temperature now was only 100°F, he seemed to have little respiratory distress, and he had no pain. The next morning — really, we were dealing with a strange disorder — the little rascal, standing on the window sill and thumping on the pane, greeted me smilingly, but I thought derisively, as I walked up the garden path. I examined him carefully and could find nothing to account for the happenings of the previous day, I told his mother that I had no idea what had been the matter with her boy but that his troubles were now over and that she should worry no more. This was an extremely rash remark, as I was to learn later, for on the next day I found the boy very much as he was on the first day of his illness, and he had several hours of distressing symptoms with the addition of pain in his back, which prevented him from raising himself from the bed. On the next day his evening temperature was 99.8°F, but thereafter he completely recovered. The family consisted of father, mother and three little boys in addition to the first victim, and the boon companions of the boys were three little girls who lived on the other side of the main road. Two of these were bending over the little sufferer's couch with interest and solicitude on the very first morning of the illness. I told the mother that these

young women were better off in their own home until we decided what was the matter with her own child and packed them off, little thinking that the damage was already done. To cut a long story short, two of the brothers were attacked on the second and third days respectively of the first boy's illness, and the two little girls on the fourth day. Four days after his boy's complete recovery the father contracted the disease.

We were therefore dealing with an infectious disease quite unknown to us, in which our textbooks gave us no assistance and two problems presented themselves for solution. Where did this strange disease come from, and could we give it a name? The first was partially answered immediately. Four days before the appearance of the illness in the first child, 2 children were brought from the York neighborhood and spent a day on the farm. I was told that one, a little girl, spent it sobbing with pain doubled up on the sofa, and although I did not see her I have no doubt that she was the infecting party. The second problem was more difficult but was eventually solved completely. I had the good fortune the previous year to be in correspondence with Dr. Ejnar Sylvest, a general practitioner of Copenhagen, on the subject of epidemic jaundice, and he very naturally sent me articles on a condition he called "myositis epidemica" or "Bornholm disease." I was unable to read his article in Danish, but his references to epidemic pleurodynia, epidemic pleurisy and above all epidemic diaphragmatic spasm made me suspect that I was on the right track. Finally a copy of his paper submitted to the International Office of Hygiene settled the matter without a shadow of a doubt. I have had further experience with this disease and have seen in all 28 patients. Three points in diagnosis I should like to stress are the greatly increased respiratory rate, whether the pain is thoracic or abdominal, the almost invariable absence of vomiting, and the rarity and lack of prominence of cough.

This, then, is Bornholm disease, epidemic myalgia or as it is called in America, "the devil's grip," a disease of alarming symptoms but with no death rate whose only danger is that it may and has indeed come under the care of the surgeon through lack of diagnosis.

#### COUNTRY BELIEFS

I wonder if a few words on the usefulness of the beliefs of the countryside would interest you in the way they interest me. I recall the story of a saucy little milkmaid who declared to her companion, in the pride of her youthful beauty, "I shall never get smallpox, I shall never have an ugly pock

marked face, I've had cow pox and girls who have had cow pox never catch smallpox" Jenner overheard this conversation and consulted his old chief, the great John Hunter, whose advice not to accept theories or jump to conclusions led to one of the basic discoveries in medicine. William Withering's old country woman selling her dropsy cure—country minds work on simple lines—had no doubt that it was a dropsy cure, and it is still a dropsy cure after the lapse of two centuries. My own district two or three generations ago cherished a dropsy cure—"pellitory of the wall." I have seen it growing in the neighborhood of an ancient castle, at Fountains Abbey, our best preserved Cistercian Monastery, and in New College Lane at Oxford, and I believe that in both it is an escape from a medieval herb garden. It is said to have been brought from the East at the time of the Crusades. In 1 case, an elderly colleague tells me, the diuresis it produced was so alarming he was called in to stop it. I must record that the link between chicken pox and shingles was accepted

quite naturally by our country folk long before it became a commonplace in the textbooks of medicine

\* \* \*

I do hope I have been able to pass on to you a little of the atmosphere of a busy country practice in England, and as I speak from thirty-seven years' personal experience, it is a full and happy life. It may, of course, be a mere repetition of irksome tasks, but this is probably the fault of the practitioner who, like Bunyan's man with the muck rake "rakes to himself the straws and sticks and dust of the floor and can look no way but downward regardless of the crown which is being held above his head." I finish with a quotation from a letter of T. H. Huxley, the advice in which is so hard to follow—

Sit down before fact as a little child, be prepared to give up every preconceived notion, follow humbly and blindly wherever nature leads, or you shall learn nothing.

## RADIOACTIVITY AND URINARY-TRACT CALCULI

DAVID S. CRISTOL, M.D.,\* ALBERT E. BOTHE, M.D.,† AND PAUL W. GROTZINGER, M.D.‡

PHILADELPHIA

**A**n interesting observation promises to open other avenues of approach in the methods for investigating the formation of urinary-tract calculi.

A patient who proved to have a vesical calculus as well as multiple prostatic calculi recently came under our care. In the course of the physical examination he was also found to be suffering from polycythemia vera. In an effort to bring the blood hematocrit within normal limits prior to surgery, it was decided to subject the patient to radioactive phosphorus therapy and thereafter to observe any changes in the size and configuration of the calculi. In preparation for surgery, two doses of radioactive phosphorus were given orally. The first dose contained 6 millicuries, and the second, administered five months later, 10 millicuries. Periodically during the seven-month period before operation, the calculus was observed radiographically and cystoscopically and appeared to grow larger. The bacterial and chemical constituents of the urine were also repeatedly examined both before and during the course of therapy. Blood counts were made at regular intervals, and when the hematocrit appeared optimal, one of us (D. S. C.) performed a suprapubic removal of the vesical calculus, together with

a revision of the vesical neck. At the time of surgery, as many of the prostatic calculi as could be

FIGURE 1 *Autoradiograph of Intact Vesical Calculus (Twenty-Four-Hour Exposure)*

dislodged from their position adjacent to the prostatic capsule were also removed.

These calculi were removed on the sixty-first day after the second oral dose of radioactive phosphorus. Immediately afterward they were bathed in water

#### COUNTRY BELIEFS

I wonder if a few words on the usefulness of the beliefs of the countryside would interest you in the way they interest me. I recall the story of a saucy little milkmaid who declared to her companion, in the pride of her youthful beauty, "I shall never get smallpox, I shall never have an ugly pock

lished a diagnosis of polycythemia vera within the previous 3 months. The patient had been bled on several occasions, with temporary relief from the symptoms.

Physical examination gave negative results except for dusky complexion, coronal hypospadias and a moderately firm and enlarged prostate with numerous crepitant areas.

The blood pressure in both arms was 160/100. Examination of the urine revealed a moderate trace of albumin, and the sediment was loaded with erythrocytes and leukocytes. A gram stain disclosed numerous gram-positive cocci and diplococci.

An excretory urogram demonstrated a vesical calculus, numerous prostatic calculi and an essentially normal-appearing upper urinary tract.

Cystoscopy revealed 100 cc. of residual urine, minimal trabeculation, a yellow, smooth, egg-shaped calculus measuring approximately 4 cm in length and 3 cm in its widest diameter, a moderate degree of trilobar intraurethral prostatic hyperplasia, numerous dilated prostatic ducts and subacute cystitis over the trigone.

After a blood count had been made, the patient was given 6 millicuries of radioactive phosphorus orally on January 9, 1947. The urine, as well as the blood, was repeatedly examined. The vesical calculus was also repeatedly observed both radiographically and cystoscopically. On May 10 radioactive phosphorus in a dose of 10 millicuries was given orally.

The hematocrit became normal, and the patient was hospitalized on July 8. A roentgenogram of the chest was normal. The urea, sugar, calcium, phosphorus, proteins and alkaline and acid phosphates were all within normal limits. The blood serologic findings were negative. On July 11, under spinal anesthesia and through a suprapubic incision the bladder was opened and the vesical calculus as well as some pros-

tatic tissue containing calculi was removed. The pathologist reported that the removed prostatic tissue represented benign prostatic hyperplasia. The patient made an uneventful recovery and left the hospital free from urinary symptoms 5 weeks after operation.

A follow-up re-examination 3 months later revealed the urinary tract to be entirely within normal limits except for the presence of some residual prostatic calculi.

## DISCUSSION

In addition to the dramatic and graphic representation of stone formation, the employment of the radioactive element may prove to have many worthwhile uses in the study of urinary-tract-calculus formation. This method might serve as a check on various proposed methods of preventing additional stone formation. It gives an opportunity for one to observe, for example, the effect of an acid ash diet on the formation of alkaline stone. It also suggests the study of the effect of radioactive materials on associated urinary-tract infections. The possible effects of residual radioactivity in calculi on the containing tissues are also under investigation.

This is apparently the first recorded case of removal of a radioactive calculus.

Medical Tower Building

## PREMEDICATION AND ANESTHESIA IN OBSTETRICS\*

### Current Practices at the Boston Lying-in Hospital

BERT B. HERSHENSON, M.D.†

BOSTON

THE first recorded obstetric operation under anesthesia in the Americas was performed by Dr. Walter Channing on May 5, 1847, at the Boston Lying-in Hospital. He wrote of his book, which was published in 1848<sup>1</sup> and which has become a classic, that "it treats of a noble subject, the remedy of pain" in childbirth. Today, a century later, this subject is still well deserving of consideration.

At the Boston Lying-in Hospital, there has been an evolution through various developmental phases of the subject. The keynote has always been the practice of safe relief of pain, permitting the obstetrician to carry on a conservative policy in the conduct of labor. All the known regional and inhalational anesthetic agents and technics have been employed, and all routes of the body have been utilized for the introduction of amnesic and analgesic drugs. At one time or another, Simpson's and Channing's methods of ether inhalation, John Snow's chloroform *à la reine*, intermittent nitrous oxide through long hours of vigil, twilight sleep and most of the pharmacologic agents known

for their effects on the central nervous system have been administered.

Out of this experience certain facts appear significant. First and most important is the obstetric team and the environment under which it functions.<sup>2</sup> The greatest emphasis should be placed on the knowledge, experience, skill, judgment, attention and mutual professional confidence of the members of the obstetric team rather than on the agent or technic employed. Secondly, the complete individualization of selection of agents, dosage and routes of administration in the able hands of a well trained team of obstetrician and anesthesiologist is the only true path to safety. Thirdly, the ideal agent or combination of agents is not available to meet all the requirements necessary for safe, controllable and effective obstetric amnesia, analgesia and anesthesia. Finally, we have been impressed with the fact that our most successful methods have included the use of scopolamine.<sup>3</sup> Its advantages and disadvantages for the obstetric patient have been dealt with elsewhere.<sup>2</sup>

We are of the opinion that misuse of analgesic drugs in obstetrics is more productive of ill effects

\*Presented at a meeting of the Merrimack County Medical Society, Concord, New Hampshire, April 7, 1948.

†Director of anesthesia, Boston Lying-in Hospital.

for forty-eight hours to remove the residual dried radioactive urine. Then they were placed before a Geiger counter,\* and the degree of radioactivity

window of the Geiger tube was recorded from the vesical calculus. The cosmic background count was 30 per minute. Autoradiographs were then made using four-hour and twenty-four-hour exposures of the intact vesical calculus and of the divided vesical calculus. A blackening of the film of the intact stone (Fig 1) was obtained, with a rather hazy border that was due to the fact that the stone was somewhat semicircular in shape and that there was some scattering of the beta rays at the margin. The stone was then cut in half in its long dimension, and the flat surface placed on a film first for four hours and then for twenty-four hours as before. A ring-like area of blackening was obtained, with a

FIGURE 2 *Autoradiograph of Divided Radioactive Vesical Calculus (Twenty-Four-Hour Exposure)*  
Intense area of blackening at the periphery represents deposited radioactive phosphorus

recorded. The vesical calculus proved to be markedly radioactive. The prostatic calculi, which were not in contact with the urine and also were

FIGURE 3 *The Divided Vesical Calculus, with a Portion of the Radioactive Lamina Removed*

presumably not enlarging during the period of phosphorus therapy, were not radioactive. A count of 2000 per minute at a distance of 10 cm from the

\*Dr. John H. Freed of the University of Pennsylvania Radiology Department, performed the radioactivity measurements.

FIGURE 4 *Roentgenogram before Operation*

somewhat hazy border. An intense area of blackening, which represented deposited radioactive phosphorus, could be seen (Fig 2) at the outermost periphery. No radioactive phosphorus was deposited in the central portion. Thus, one has a true picture of the radioactive phosphorus in the stone and an estimate of the increase in the size of the stone during the time when the patient was receiving the drug. Figure 3 shows the divided stone, with a corresponding radioactive lamina chipped off from the lower half. Figure 4 reveals the flat plate, including the renal, ureteral and vesical areas before surgery. Further details are presented below.

#### CASE REPORT

A S., a 56-year-old man, was first seen in December, 1946, complaining of marked diurnal and nocturnal urinary frequency, dysuria and intermittency of urination that had progressed over a period of approximately 2 years. During the previous 4 months, he had also suffered numerous hot flushes, frontal headaches and periodic episodes of vertigo.

The past history was none contributory except for the fact that a physician had treated him for 6 months as a suspected case of pulmonary tuberculosis 30 years before and had estab-

If more advanced renal-function impairment exists the drugs for premedication are omitted, or reduced to one fourth the usual dosages. The delivery is completed under a regional analgesic procedure, and the patient is provided with oxygen-enriched atmospheres.

#### *Gastrointestinal Complications*

If a patient has had food or fluid within six hours of hospital admission, she is considered as presenting the complication of a "full stomach." It must always be remembered that fluid or food in the stomach is compatible with life, but in the lungs means death. If delivery is imminent the patient's stomach is washed out, and to make certain that the procedure is successful she receives but half the usual dosage of barbiturates and the first dose of apomorphine is 1.2 mg instead of the usual 0.6 mg. When the foregoing procedures have been effective in emptying the stomach, the patient receives the usual premedication and anesthesia. In the event that the preanesthetic preparatory procedures have been ineffective in emptying the stomach, the plan is to retain consciousness and protective reflexes by employing a regional analgesic block for the termination of labor and the completion of the delivery.

In cases requiring operative abdominal or other surgery during the course of pregnancy, the plan of premedication and anesthesia is decided upon an individual basis and after consultation between the surgical consultant and the anesthesiologist.

Hospitalized patients are not permitted food or fluid by mouth during labor. Fluids are administered parenterally, as indicated, to meet the patient's physiologic requirements.

#### *Central-Nervous-System Complications*

In premedication the drugs, dosages and routes are employed as for the uncomplicated case. Individualization is the basis in actual practice.

Regional analgesia and the use of solid anesthetic agents are contraindicated in this group of cases. An inhalational anesthetic procedure is planned for the following problem cases: patients with a previous history of headache or backache, patients with a suspected, or known, lesion of any part of the nervous system, and patients presenting a history of previous difficulty with regional anesthesia.

#### *Metabolic Disturbances*

**Diabetes.** The plan of premedication is essentially the same regarding selection of amnesic and analgesic drugs, but the dose is reduced so as to avoid loss of consciousness. The purpose is to utilize the aid of the patient during administration of a regional block for the termination of labor and delivery.

**Hyperthyroidism.** The agents employed for premedication are the same, but the dose is increased by one eighth to one fourth the amount, the interval and routes of administration remaining the same. The anesthetic procedure of choice is inhalation, employing oxygen-enriched atmospheres.

#### *Specific Obstetric Complications*

For patients who are to have cesarean section or "double set-up" examination to determine the cause of late antepartum hemorrhage, premedication consists of the administration of 0.2 gm of sodium amytal by mouth, or rectum, two hours preoperatively, scopolamine and apomorphine 0.6 mg of each, are injected intramuscularly one hour later. The anesthetic procedure of choice is inhalation—otherwise, there is a consultation by the attending obstetrician and the anesthesiologist.

For patients presenting the problem of prematurity or suspected immaturity of the fetus, premedication consists of a minimal dose of a barbiturate, usually 0.1 gm of seconal one hour before delivery, followed by a regional analgesic procedure.

For patients who are to have a test of labor the plan of premedication is essentially the same as that for the uncomplicated case, but the dose of drugs is reduced by half. If the delivery is completed vaginally, the choice of anesthesia is an inhalational procedure. Otherwise the case is treated on an individual basis.

In patients with pre-eclampsia or eclampsia, if the case is one of mild or Grade I pre-eclampsia premedication and anesthesia are planned as for the uncomplicated case to be delivered vaginally, in the absence of other complications. The severer cases presenting this obstetric complication are individualized. If premedication is employed demerol in doses of 50 to 100 mg every three or four hours intramuscularly is administered and light inhalation anesthesia with highly enriched oxygen atmosphere is used for the delivery. When possible the delivery is completed under the premedication alone, any further depression or interference with vital functions being avoided. It is important to remember that a "whiff" of gas alone is a dangerous procedure. Intravenous anesthesia and nitrous oxide (or either procedure alone) are contraindicated for this group of cases. If regional anesthesia is to be employed, the decision rests on consultation between the attending obstetrician and the anesthesiologist. In any case the guiding principle is that safety must never be sacrificed for comfort or convenience.

#### SPINAL ANALGESIA

When we employ one of the methods of regional anesthesia we are governed by the presence of a definite indication. This policy is best illustrated

upon both mother and baby than properly administered inhalational anesthetic agents. Judicious selection and skillful administration of inhalation anesthetic agents are most successful for the termination of labor. Among some of the advantages of inhalation anesthesia are the rapidity of exchange of agent via the lungs, short induction and recovery periods, predictable and controllable depth and duration of anesthesia, retrievableness of the agent without residual injury, wide margin of safety, lack of extra load on the detoxifying mechanisms of the body and permissibility of employment of highly oxygenated atmospheres.

We employ regional and inhalational anesthetic procedures. The selection of agent and technic is based on many factors, some of the more important of which are physical status of the patient, the gestational age and condition of the fetus, the degree of muscle relaxation necessary to complete a given obstetric procedure, the duration and depth of narcosis required, the action of the agents selected and their influence on the conduct of labor and the skill and experience of the obstetrician and anesthetist.

For the purposes of guiding the resident and house staff in the selection of premedication and anesthetic procedures the outline presented below has been devised.

#### UNCOMPLICATED VAGINAL DELIVERY

Early in labor following the admission enema, the patient receives 0.1 gm of scopolamine, usually by mouth, for the purposes of determining sensitivity to barbiturates and to provide some psychic sedation. If no untoward reaction exists she receives 0.1 gm of scopolamine along with 0.1 gm of sodium amytal at the end of an hour by mouth or rectum. If the latter route is used the ends of the capsules are perforated before administration. At that time 0.6 mg of scopolamine hydrobromide is administered intramuscularly. The total dosage of barbiturates during labor is limited to 0.4 gm.

As labor progresses and becomes more active so that the patient complains of painful contractions of the uterus, intramuscular injections of scopolamine and apomorphine of 0.6 mg each are given, followed in an hour by an intramuscular injection of 0.4 mg of scopolamine and 1.2 mg of apomorphine. The latter dosage combination of scopolamine-apomorphine is administered intramuscularly every two hours until the patient is ready for delivery. In the event that the patient shows muscular overactivity or agitation (scopolamine reaction), additional doses of 0.6 to 1.2 mg of apomorphine are administered intramuscularly and may be repeated at intervals of fifteen minutes until the desired therapeutic response is reached. This is rarely more than two doses.

The delivery is completed under an inhalational procedure. A clear, unobstructed airway must

be maintained constantly. Any cause inhibiting normal thoracic excursions must be eliminated. Employment of highly oxygenated atmospheres is encouraged, until the delivery of the fetus is completed and the cord is clamped. At the completion of anesthesia and delivery, the nurse is instructed to turn the patient on her side to drain any secretions, at the same time the patient's head is slightly extended. An unconscious patient constantly demands careful and intelligent supervision and protection.

#### SPECIAL PROBLEMS

##### *Respiratory Complications*

For patients with active respiratory infections, such as upper-respiratory-tract infections with temperature or cough, premedication consists of the measures outlined above for the uncomplicated case, but the barbiturates are reduced to half the dosage outlined, or less. Delivery is completed under the plan of premedication or supplemented with a regional block, usually low spinal analgesia. The spinal analgesia is administered by a member of the resident staff or under the supervision of the anesthesiologist.

For patients with asthma the barbiturates are reduced to a minimal dosage range, not exceeding 0.03 to 0.2 gm of scopolamine and apomorphine are administered as outlined above. The delivery is completed under inhalation anesthesia, ether being employed as the agent of choice. A skin test with the drugs and anesthetic agents before administration is given to any patient suspected of having asthma or of being allergic.

Patients with previous thoracic operative procedures or with active tuberculosis are treated as for active respiratory infections.

##### *Cardiovascular (Circulatory) Complications*

Both premedication and anesthesia are individualized for patients with Class IA cardiac disease (unfavorable cardiac cases).

For those with Class I cardiac disease (favorable cardiac cases), medication consists of administration, intramuscularly, of 100 mg of demerol when the patient is in active labor and thereafter of 50 to 100 mg of demerol every three or four hours. Inhalation anesthesia is employed for termination of the labor. After delivery the patient receives oxygen-enriched atmospheres as indicated.

Patients with Class II and III cardiac disease (functional) are treated like those with uncomplicated vaginal delivery, untoward manifestations being watched for.

##### *Genitourinary Complications*

If moderate to mild impairment of renal function exists the dosages of the drugs used for premedication are reduced to one half. The delivery is completed under inhalation anesthesia.

is withdrawn, and the needle and syringe examined. A sterile dressing is applied to the puncture site. The patient is turned on her back, with one or two pillows under her upper back, neck and head. The level of analgesia is frequently tested, and the patient cautiously positioned, as indicated. The patient is leveled when the desired height is reached, that is the tenth dorsal dermatome for pelvic deliveries and the sixth to the fourth dorsal dermatome for abdominal delivery.

#### *Therapeutic and Prophylactic Measures*

The clinical course of the patient is checked, and at intervals of at least five minutes the blood pressure, pulse rate, respiratory rate and volume are recorded. Intercostal breathing, the development of pallor and other skin changes, disorientation or other changes in behavior, nausea or emesis, thirst, air hunger, palpitation, precordial distress and other psychosomatic changes are watched for.

The patient is supplied early and immediately with air that is highly oxygen enriched. Carbon dioxide is avoided, for it only increases the vascular dilatation and augments spinal shock. An adequate airway is watched for and maintained, the thorax is inflated manually via the rebreathing bag with oxygen, should intercostal paralysis exist.

The use of the Trendelenburg position is avoided until the anesthetic agent is fixed — that is for 25 to 30 minutes after induction.

Measures are instituted to support depressed respiration and circulation at once. Venoclysis or transfusion is employed promptly as indicated. During acute hemorrhage there is no substitute for compatible whole-blood transfusion.

Supplementary anesthetic agents and technics are employed when indicated. Adequate assistance, suction, oxygen, fluids, drugs (ephedrine sulfate, prepared) and indicated agents must be available constantly. The patient must be watched by the anesthetist responsible for the case, and knowledge must be had of all the patient's psychic, psychosomatic, somatic and reflex responses constantly.

#### DISCUSSION

It should be emphasized that about 80 per cent of our deliveries are completed by the use of in-

halational anesthesia. Under inhalational technics are included open-drop ether and semiclosed and closed carbon dioxide absorption methods, both circle-filter and Waters to-and-fro procedures. We stress the use of oxygen-enriched atmospheres, especially during the terminal portion of the second stage of labor. The delivery is actually accomplished in the topmost portion of the first plane of the third stage in accordance with Guedel's classification of the stages of anesthesia. The accumulation of carbon dioxide, even in the presence of oxygen-enriched atmospheres, is neither encouraged nor desired.

In another paper<sup>2</sup> several case histories of vaginal deliveries are presented as typical of our current practices of premedication and anesthesia. The drugs are essentially the same in all cases. The method of delivery with reference to the terminal anesthetic procedure is different in each case. The problems presented by each patient during her period of hospitalization are discussed in some detail.

#### SUMMARY

The current practices of premedication and anesthesia at the Boston Lying-in Hospital are presented and discussed. Emphasis is placed upon the knowledge, experience, skill, judgment, attention and mutual professional confidence of the team, composed of the obstetrician and the anesthesiologist and their co-workers. The keynote is the practice of safe relief of pain permitting application of a conservative policy in the conduct of labor. Over 80 per cent of our deliveries are completed under inhalation anesthesia. The advantages of inhalation anesthesia are discussed. An outline of the conduct of premedication and anesthesia with reference to the obstetric problem is presented.

The policy regarding regional analgesia is considered. An outline of indications, contraindications, technic, agents, therapeutic and prophylactic measures for spinal analgesia in obstetrics is included.

by a brief consideration of spinal analgesia as currently used at the Boston Lying-in Hospital

### *Indications*

When the patient presents one or more of the following complications spinal analgesia constitutes the usual practice in the termination of delivery, respiratory complications, including fever or cough, a recent meal, when delivery is imminent and unconsciousness may be a threat to life, fetal distress, when further depression is best avoided, prematurity or immaturity of the fetus, diabetes mellitus, particularly if severe or uncontrolled, and other complications, such as a surgical procedure other than obstetric. The final decision rests between the attending obstetrician or consulting surgeon and the anesthesiologist.

### *Contraindications*

We consider that the majority of obstetric cases fall in this group, and may be listed as follows: known or suspected disease of the central nervous system, such as tumors, hemorrhage or lesions of the brain or spinal cord, syphilis of the central nervous system, pernicious anemia involving the nervous system and other pathologic processes involving the parenchyma or coverings of the central nervous system, infection of the skin at or close to the point of spinal puncture, known history of headaches or backaches, mental aberrations such as psychoses and psychoneuroses or marked fears or anxieties, congenital anomalies—for example, pilonidal cysts and spina bifida—or other malformations of the structures about the spinal column, hemoglobin of 50 per cent or less, cardiovascular disease, labile vasomotor system or unstable autonomic nervous system, marked malnutrition, septicemia, hemorrhage or shock, known allergic responses to solid anesthetic agents, or previous history of undesirable experience with a regional anesthetic, marked obesity, serious uterine complications, such as uterine apoplexy, rupture and hemorrhage, necessary intrauterine manipulation—for example, internal podalic version or breech delivery, abnormal spinal fluid—turbid, cloudy or bloody spinal tap (also, patients with increased spinal-fluid pressure, for this may mean a block in the spinal canal), fear of post-spinal sequelae, and other patients so considered by the attending obstetrician in consultation with the anesthesiologist.

### *Technic and Agents*

Evaluation of the patient, her disease, state of maturity of the fetus, and previous anesthetic experiences should be made. Premedication consists of the administration of 0.1 to 0.2 gm of sodium amytal two hours prior to delivery and 50 to 100 mg of demerol one hour later injected intramuscularly. The patient's blood pressure, pulse rate

and respiratory rate and character are noted and recorded on the obstetric anesthesia study sheet. The patient is then placed in the lateral or sitting position and supported by an assistant. The skin over the lumbar portion of the back is prepared with ether, followed by tincture of zephiran, and sterile towels or sheets are applied. With sterile gloved hands the site of puncture is located, the third or fourth lumbar interspace being used. Ampoules are examined for cracks, only ampoules that are clear and colorless being used. A wheal is raised with a 0.5 per cent procaine containing not over 50 mg of ephedrine sulfate. If an allergic response is elicited the spinal analgesic procedure is discontinued. Otherwise, the path to and including the interspinous ligaments is anesthetized. Flexible needles with short bevel and properly fitting stylets are employed for the spinal tap, the needle being tested before use. The bevel is inserted caudad. A spinal needle of 20 to 22 gauge is selected, if the needle is made of gold or platinum, the gauge should be 22 to 24. In the latter instance a groove director is previously inserted into the spinous ligaments. The needle is slowly introduced with the stylet into the dural sac and thence into the subarachnoid space. The stylet is carefully withdrawn, and clear fluid should appear. The procedure is discontinued if the spinal fluid is bloody, turbid or cloudy, or if under abnormal pressure. Otherwise, with the needle held fixed in place, the anesthetic solution is slowly injected at an approximate rate of 0.25 cc per second. The anesthetist should always be on the alert for any untoward reactions. Our selection of agents is limited to the following:

For pelvic delivery procaine hydrochloride, 50 to 100 mg in a concentration of not over 5 per cent is used, with spinal fluid as the diluent. The expected duration is approximately from one to one and a half hours and not infrequently longer. The height of sensory analgesia is governed by the rate of injection, dilution, amount of drug, interspace employed and positioning of the patient as the more controllable variables. We avoid barbotage. If saddle block is desired, injection is performed slowly, and the sitting position is maintained about 3 to 5 minutes, the level being frequently tested. For abdominal delivery the agent of choice is procaine hydrochloride, 100 to 150 mg in 5 per cent dilution. The duration of effect may be expected for one to one and a half hours. If a longer duration is required, this being a teaching service, pontocaine hydrochloride (5 to 8 mg) with procaine hydrochloride (50 to 100 mg) is resorted to. In that case we prefer to limit the dose of pontocaine to 5 mg, and in any case the concentration of drugs injected is not over 5 per cent. At the end of the procedure the needle

The patient was last seen on July 17, 1947, when the hemoglobin was 34 per cent and the red-cell count 3,120,000. She had experienced several slight episodes of bleeding since leaving the hospital. Rutin therapy is now faithfully followed.

### DISCUSSION

This patient presented the typical findings associated with familial hereditary hemorrhagic telangiectasia. The life-long history of nosebleeds, increasing in severity with advancing years, together with the presence of multiple telangiectatic areas on the skin and mucous membranes established the diagnosis without question. It is unfortunate that a definite familial incidence could not be traced. The history of the deceased brother who had nosebleeds is suggestive, but vague, and impossible to substantiate. The possibility that the patient had some admixture of white blood cannot be ruled out, of course, even though she had no knowledge of Caucasian consanguinity.

Whether the profound anemia was the result of the epistaxes alone, or the result of additional bleeding from lesions in the gastrointestinal tract is a matter for speculation, for such lesions do occur frequently. It was believed that the potential danger involved in gastroscopy of such a patient was too great to warrant the procedure.

Although no treatment is entirely satisfactory in these cases, the administration of rutin appears to have been of some benefit, the use of snake venom was apparently without avail.

### SUMMARY

A case of hereditary hemorrhagic telangiectasia occurring in a forty-eight-year-old Negress is presented, no previous report in a Negro being available.

The administration of rutin appears to have been of some value in this case.

## MEDICAL PROGRESS

### PLASTIC SURGERY

#### Skin Transplantation

BRADFORD CANNON, M.D.\*

BOSTON

THE essence of plastic surgery is the transplantation of tissue. Skin is the one most commonly transplanted. It is therefore proposed to review the development of the methods of skin transplantation that have led to some of the modern principles on which the present management of plastic surgical problems is based. In any young surgical specialty much emphasis is placed on methods and techniques, which, as they improve and are standardized, pave the way for the formulation of basic principles that apply in the broadest sense. Many of these principles bear directly on all phases of reconstructive surgery, but particularly on the surgery of trauma. Their elaboration has been stimulated by the concentrated experience of plastic surgeons in caring for war casualties, as well as by varied and extensive experiences in civilian reconstructive surgery.<sup>1-4</sup>

Skin transplantation is carried out in two basic ways: free transplantation or skin grafting, which means that the skin is completely detached from the body in its transfer, and transplantation as a flap, which means that at all times the skin and subcutaneous tissue remain attached to the body and receive blood supply through this attachment

or pedicle. The free skin graft must be thin, without any subcutaneous tissue, to survive and grow after transfer, whereas the flap must retain the subcutaneous tissue in which the nutrient vessels of the skin lie.

In the primary or secondary closure of traumatic or surgical wounds and in the resurfacing of scarred areas, the simplest, most effective approach is desirable. Four principal methods are generally used, the indications for which are frequently emphasized in the papers reviewed for this report on skin transplantation. The first and simplest closure is by direct suture, which implies an adequate amount of healthy skin to allow approximation of the edges without tension. The second method is by a free skin graft. The split skin graft is readily available, and since the donor area heals within two weeks,<sup>5</sup> no additional deformity results. The graft will take on a well prepared granulating wound, such as that resulting from a burn, but may not survive on an avascular surface of scar tissue such as that underlying a thin layer of excised scar epithelium or that in an area with deep radiation damage. It will usually grow on cancellous bone but seldom on cortical bone.

The free skin graft has widespread usefulness as a primary skin dressing of large and small un-

## FAMILIAL HEREDITARY HEMORRHAGIC TELANGIECTASIA IN THE NEGRO\*

## Report of a Case

STEVEN O. SCHWARTZ, M.D.,† AND BERTHE E. ARMSTRONG, M.D.‡

CHICAGO

**B**ECAUSE familial hereditary hemorrhagic telangiectasia in the Negro has not been previously described in the literature, it was believed that the following case deserved mention.

A 48-year-old Negress first entered the Cook County Hospital on October 31, 1945, because of a nosebleed lasting 8 hours. She had had frequent epistaxes all her life, and 2 weeks before admission had noted vertigo, syncope and edema of the face and feet. The nosebleeds had occurred at intervals "as long as she could remember" but had been inconsequential until the menopause, at the age of 42. During the next 4 years they increased both in frequency and severity until at the time of admission she was averaging three episodes a week, each one lasting from 3 to 9 hours. There was also a history of bleeding from the tip of the small finger of the right hand on two different occasions about 1½ years previously. There was no recurrence of this bleeding after she learned to guard this spot from trauma. The menstrual periods were regular with a moderately heavy flow until the menopause. There had been no post-menopausal bleeding. She had been pregnant twice, one pregnancy terminating in a destructive operation because of a dystocia, and the other in the normal delivery of a healthy child.

The past history was eventful but had no relation to the present episode.

No familial history of bleeding could be elicited, with one exception, that of a brother, recently dead of "heart trouble," who had had moderately severe nosebleeds once or twice a year. Efforts to communicate with members of the family were unsuccessful. Inquiry into the racial background failed to reveal any known admixture of white blood, but the maternal grandmother was said to have been an American Indian.

Physical examination showed the patient to be well developed and well nourished, she appeared much younger than her chronologic age. She was intelligent and co-operative and did not appear acutely ill. There was continuous bleeding from the nose. The mucous membranes were extremely pale. Multiple small, bright-red areas varying in size, the largest approximately 3 mm in diameter, were present on the tongue, buccal mucosa, gums, soft palate, face and chest. A similar spot was present under the tip of the nail of the small finger of the right hand. The lungs were normal. The heart was enlarged, the apical beat being visible 9 cm to the left of the midclavicular line in the sixth interspace. A loud, harsh systolic murmur was heard over the entire precordium, but was loudest in the third interspace. The liver was palpable 7 cm below the costal margin and was firm and smooth. A firm, slightly tender mass, about 3 or 4 cm in diameter, was palpated in the right lower quadrant of the abdomen. On pelvic examination this was found to be connected with the right adnexa. Examination of the nose revealed bleeding from the right Kiesselbach's area. This was treated with silver nitrate, and the nose was packed.

The temperature was 98.6°F, the pulse 88, and the respirations 20, the blood pressure was 120/75.

Examination of the blood revealed a red-cell count of 1,560,000, with a hemoglobin of 13 per cent (20 gm.), and a white-cell count of 5050, with a normal differential. The

red cells were microcytic and markedly hypochromic, with moderate anisocytosis and poikilocytosis. The bleeding time was 1 minute, 35 seconds, and the coagulation time 8 minutes (by the multiple tube method), prothrombin activity was 90 per cent, and the platelet count was 217,500. Urinalysis, blood Kahn and Wassermann tests and x-ray examination of the colon were negative. The nonprotein nitrogen, total serum protein and cevitamic acid determinations from time to time revealed no significant information.

Moderately severe epistaxes occurred at intervals during the following 10 days but were controlled by packing. The patient received 2000 cc of whole blood during this period. She left the hospital on iron therapy on November 19, feeling well but still moderately anemic (on November 19 the red-cell count was 4,280,000, and the hemoglobin 72 per cent).

She was readmitted to the hospital on January 23, 1946, with a history of massive hemorrhages from the nose for several days. Physical examination was essentially the same as previously.

Examination of the blood disclosed a red-cell count of 1,080,000, with a hemoglobin of 11 per cent (17 gm.), and a white-cell count of 12,400.

The bleeding was again treated locally with silver nitrate, and she received 500 cc of whole blood. As no further bleeding occurred during the next 10 days, she was transferred to the dermatology ward for treatment with moccasin venom intradermally. This she received twice weekly in doses ranging from an initial dose of 0.1 cc. up to 1.0 cc. In spite of this treatment the epistaxes recurred, became both frequent and severe, and required packing. Two 500-cc blood transfusions were given during that time. On March 24 a new telangiectatic area was noted on the ball of the right thumb. On April 3 the patient was discharged to the dermatology outpatient clinic for further treatment.

The patient was readmitted to the hospital on September 3. There had been three severe nosebleeds since discharge, and she had experienced progressively increasing weakness, which had necessitated confinement to bed for the preceding 2 months. Nausea and vomiting had been present for 4 hours during the night before admission. Examination of the blood disclosed a red-cell count of 1,090,000, with a hemoglobin of 9 per cent (14 gm.), and a white-cell count of 7950. She was given 1000 cc of whole blood immediately and placed on iron therapy. Further treatment was hampered, as in the past, by the difficulty of obtaining blood donors. Moccasin venom was continued in doses from 0.4 to 0.8 cc. Three weeks after admission she left the hospital against advice, although her condition was very little improved and she was still experiencing frequent and severe epistaxes.

She was again admitted on March 31, 1947, with complaints of edema of the face and legs for 2 weeks and epistaxis for 12 hours. The red-cell count was 1,600,000, and the hemoglobin 21 per cent (33 gm.). She was given a transfusion of 500 cc of whole blood and rutin<sup>§</sup> was administered in a dosage of 20 mg four times daily. Only a few minor hemorrhages occurred during this hospital stay, and at the time of discharge from the hospital at the end of April the red-cell count was 3,210,000, and the hemoglobin 53 per cent.

On June 16 the patient re-entered the hospital after two severe nosebleeds during the previous 3 weeks. She had not been taking rutin during the interval because her supply was exhausted. The hemoglobin was again down to 23 per cent. Since no blood was available the patient was treated with iron and rutin only.

<sup>§</sup>The rutin was furnished by the Abbott Laboratories through the courtesy of Dr. Richard K. Richards.

‡Formerly research fellow, Hematology Laboratory, Cook County Hospital, Chicago.

Cleanly care of the wound itself is also important.<sup>24</sup> Frequent change of dressing, scrupulous removal of crusts, exudate and debris, and application of moderate pressure will change the appearance of a wound completely. Saline tub baths have been used frequently by Brown,<sup>15</sup> and by Allen and Koch<sup>25</sup> to aid in the preparation of large raw surfaces for closure with skin grafts. Brown<sup>15</sup> has emphasized the importance of the use of fine mesh gauze against a granulating surface. This prevents the growth of granulations into the meshes of the gauze and thus reduces the likelihood of bleeding at the time dressings are changed. He has also introduced the use of the short fiber mechanic's waste, a universally available material and one that is just as effective as the more expensive sea sponges or fluffed gauze. Mechanic's waste can be made to mold itself against an uneven surface better than other materials and furnishes the resiliency needed for immobilization and support of the granulations and the later skin graft. Antibiotics and chemotherapy are, of course, very valuable aids but cannot supplant meticulous care of the wound.

The following is a brief summary of the management of skin grafts based on the reports of those who have had the widest experience in their use. The grafting of a raw surface is undertaken only when the patient's general condition is stabilized and when the granulating surface is firm and free from active infection. This condition can be judged best by clinical evaluation of the wound.<sup>25</sup> If the granulation tissue is thin and firm, it may be unnecessary to disturb it, but usually in long-standing ulcerations or old burns it is thick and irregular and should be carefully and smoothly shaved off.

The split thickness graft obtained either with a knife or by a mechanical device is the most satisfactory graft for healing granulating wounds or for large repairs. If adequate fixation of the graft is possible with the dressing alone, the grafts can be "snubbed" in place. Otherwise, suturing may be desirable. Sometimes the Reverdin or "pinch graft" may be used but this leaves a mottling of both the donor and the recipient site. Sheets of skin cut up into small pieces of postage-stamp size and held against the raw surface by the dressing are also useful.

Either grease gauze or wet fine mesh gauze is used immediately over the graft. Support of the graft and immobilization of the part is obtained by a bulky dressing of mechanic's waste and, if indicated, a splint.

A change of dressing is usually done by the fifth day if the grafted surface was granulating. This permits inspection of the operated area, removal of any marginal necrotic skin and mechanical cleaning of the surface. If the operated area was healed, the first dressing need not be done so early, the exact time is a matter of individual preference. All sub-

sequent dressings are planned according to the condition of the grafts.

In the late care of skin grafts, supportive bandages are necessary. This is particularly true of the lower extremity until normal vasomotor tone is re-established. In large grafts this may take six to eight months. For the upper arm, where the column of blood is not long, only a short period of support is necessary. In grafts for contractures of the neck, MacCollum<sup>26</sup> has recommended the wearing of a Thomas collar to stretch the graft.

Marginal scars, in elective skin grafting following the release of contractures or following surgical excision, must be so placed that a contracture will not develop or recur. This may be done by incisions or "darts" extending out from the margin, which are grafted with the central defect. Or should there be such a contracture, it can often be released by a local shifting of flaps or Z-plastic.

Skin grafts have proved useful in extremity wounds with chronic osteomyelitis and large bone cavities. Among others, two valuable reports concerning this complex problem have appeared. Knight and Wood<sup>27</sup> have followed a three-stage procedure in obliteration of bone cavities: a thorough sequestrectomy and excision of all adjacent scar tissue, early split skin grafting of the cavity, and excision of the graft, filling the cavity with bone chips, and immediate closure with a flap either direct or prepared earlier. Kelly et al.<sup>28</sup> using the same procedure in the first two stages have found that a third stage is often not required. Their results with bone grafting of the cavity have been disappointing and they prefer using a thick abdominal flap with abundant fat to fill it. They emphasize the importance of the vascularity of the final skin covering and the limited usefulness of chemotherapy and biotherapy.

Brown and McDowell<sup>29</sup> have reported follow-up studies on a large group of skin grafts in children. They find that the grafts grow, and function persists throughout the child's development.

A recent study of sensory regeneration in transplanted skin by McCarroll<sup>30</sup> confirms the clinical impression that the rate of return is inversely proportional to the thickness of the transplanted skin. Pain sensation returns sooner than touch, and the temporal dissociation is greater with a thicker graft.

Conway<sup>31</sup> reports a qualitative study of sweating function in transplanted skin. There is sweating only when the full thickness of the skin is transplanted. In thinner grafts, the functioning portions of the glands are apparently destroyed.

Space does not permit a more detailed presentation of the many recent publications about skin grafting. Methods and principles in using skin grafts, perfected largely by American plastic surgeons, have been so simplified that they are now generally available. The successful use of these

healed surfaces,<sup>6, 7</sup> in replacing damaged or lost skin,<sup>8</sup> in the closure of burn wounds after surgical excision,<sup>9</sup> in the resurfacing of superficial scars and release of deforming scar contractures<sup>10</sup> and in many other conditions. A free skin graft may have to be replaced with a flap, or a flap used primarily, when deeper structures such as bone, tendon or nerve are damaged, or when operation on these structures is contemplated. If the condition of the deep tissues will not support a graft—for example, in a deeply penetrating wound, or when the full thickness of a part, such as the nose or cheek, is missing—a flap must be used.

The third and fourth methods available for wound closure, resurfacing of a scar, or restoration of a part are the use of a local and a remote flap.<sup>11</sup> A local flap is desirable if sufficient skin is obtainable in the vicinity without interfering with function or creating additional deformity, and a remote flap is desirable if these conditions cannot be fulfilled or if larger amounts of skin are necessary. Flaps find their greatest usefulness in reparative surgery following compound traumatic wounds, either civilian or military. Usually there is damage and scarring of the deep structures, which delays their healing and disrupts their function. The restoration of surface covering<sup>12, 13</sup> and improvement in general nutrition of the part<sup>14</sup> are the first steps in the preparation for orthopedic or other surgical repair. The deep repair can be only as successful as the surface healing. In the absence of a part, not only skin but also subcutaneous tissue is necessary for bulk. Thus the destroyed nose, cheek, finger or ear is restored with one or more flaps.

#### FREE SKIN GRAFTING

The free transplantation of skin has been practiced only during the last seventy or eighty years. Reverdin, in 1869, first demonstrated that small bits of epidermis could be transplanted to unhealed surfaces in other parts of the body. According to Koch,<sup>15</sup> Lawson was the first to transfer a sheet of skin successfully, but Ollier, Thiersch, Wolfe and Krause are more often thought of in connection with the early development of methods in transplanting skin of intermediate and full thickness.

Little except a description of "small deep grafts" by Davis<sup>16</sup> was added to the technics and understanding of free skin grafting until after World War I. The challenge of the war and the increasing interest in the initial and late care of burns led to the development and perfection of methods for obtaining large sheets of skin and to a better appreciation of the conditions necessary for successful transplantation.

The modern concept of the use of free skin grafts had its beginning in 1929, when Blair and Brown<sup>17</sup> published the first of a long series of papers. These important publications were summarized in

1943 by Brown and McDowell<sup>18</sup> in a monograph. Their basic contribution was the description of a simple, efficient method for obtaining large sheets of skin. With the use of a long thin knife and a suction box to hold the skin taut, grafts as large as 90 by 10 cm. have been cut.<sup>19</sup> This method is still standard practice with many surgeons. A moderate amount of skill and experience is necessary for the effective use of this technic. Variations in the procedure, devised to minimize the human factor, have been suggested by Marcks<sup>20</sup> and Caltagironi. The introduction of the dermatome by the late Earl Padgett<sup>21</sup> in 1939 makes it possible for surgeons with minimal experience to have adequate amounts of skin available for grafting. The dermatome is an accurately machined half-drum with a knife blade attached by radial arms to the axis of the drum. The thickness of the skin graft, which is stuck to the drum by rubber cement, is determined by the distance between the edge of the knife blade and the drum. The method immediately received widespread acceptance. Donor areas not easily adaptable to the use of a knife are available as sources of skin with the dermatome. The value is obvious in extensively burned patients. Padgett<sup>22</sup> summarized his experience in a monograph published in 1942. Several improvements in the dermatome have been suggested, all following the same principle. Webster<sup>23</sup> uses phlofilm to back the skin graft on the drum, which simplifies separation from the drum and prevents shrinking and wrinkling of the graft. May<sup>24</sup> employs nylon cloth for the same purpose. Reese<sup>25</sup> has constructed a precision dermatome and uses a rubber sheet, called "dermatape" for backing of the graft. In my experience, this is the most accurate and effective machine for cutting skin grafts yet introduced. Douglas,<sup>26</sup> by attaching a windshield wiper to the dermatome, mechanically supplied reciprocating motion to the knife.

As mentioned above, the most important and most frequent use of the skin graft is in the covering of unhealed wounds. Although many of these are the result of burns, it is not the purpose of this paper to discuss the early care of burns. Success in the skin grafting of raw surfaces depends to a large extent on management before and after operation. Seldom is a raw surface sterilized before grafting. The aim of the surgeon is to have firm flat granulations without cellulitis and with minimal drainage and minimal bacterial growth on culture. To achieve this goal, particularly in extensive areas, requires more than merely local therapy. The importance of maintaining normal protein, vitamin and electrolyte levels in the blood and a normal red-cell count and hemoglobin has been repeatedly stressed.<sup>27-30</sup> This necessitates frequent transfusions and other supportive measures to replace cells, protein and vitamins deficient in the all too often seriously debilitated patient.<sup>31-33</sup>

the nose The composite graft has been used by Armstrong and Garcia<sup>57</sup> in repairs of the eyelid margin

### HOMOTRANSPLANTATION

Ever since the first free skin graft was used the possibility of transplantation from one person to another has been the cause of much speculation and investigation At the turn of the century there were isolated reports of successful isografting or homotransplantation of skin Davis,<sup>55</sup> in his monograph on plastic surgery in 1919, reported a review of hospital records and concluded that such homotransplantation was possible Later, he was convinced that the observations were faulty One of the most enlightening reports on this whole problem is that of Loeb,<sup>59</sup> a pioneer in tissue culture Loeb considered individual biologic differences to be very specific The more closely related the species, the less marked the individuality differential which he characterized as chemical differences in the cells In isografting these differentials come into play, and the evidence indicates that a primary substance or toxin is produced by the graft that causes a reaction in the host, making the graft disappear That this is not a true immune reaction is indicated by Loeb's observation of the absence of an accelerated reaction on secondary transplantation Studies by Medawar<sup>60</sup> shed further but somewhat different light on the subject He presents contradictory evidence that the reaction to a homograft is a true immune phenomenon, with acceleration in proportion to dosage of the reaction to a second graft Medawar also reports no evidence that red cells and skin share similar antigens, although leukocytes and skin do share them Such an observation disproves the value of blood typing in homotransplantation Barker<sup>61</sup> doubts that failure of homotransplantation is on the basis of sensitization to homologous skin proteins

Stone,<sup>62</sup> in 1934, stimulated interest in homotransplantation by his studies of tissue culture of the parathyroid glands He investigated the possibility of adapting the graft by first growing it as a tissue culture in a medium containing the body fluids of the future host "This we have done in all cases in which we have secured successful grafts," he writes

Both Padgett<sup>63</sup> and Brown<sup>64</sup> have reported successful homotransplantation of human skin in identical twins An elective interchange of full thickness grafts on the upper arm was carried out by Brown One of the most recent reports was that by Converse<sup>65</sup> in which one of twins was severely burned in the leg, and skin from the twin brother was used with the patient's own skin for covering The behavior of the homografts, he reports did not differ from that of the autografts, and a two year follow-up confirms the stability of

the homografts These observations of successful transplantation between identical twins suggests a very fundamental individual cell specificity However, the fact that practically inert lymph-nourished tissues like cartilage and cornea can be permanently transplanted indicates that it pertains only to the more highly involved tissues of the human body

Recent studies by Longmire<sup>66</sup> confirm the temporary survival of homotransplants and the insignificance of blood group of donor and recipient in skin homografting He also presents evidence that, unlike blood types, skin types do not exist

Barker<sup>67</sup> reports studies of pigment changes in iso skin transplants between black and white rabbits Black skin is transplanted to white animals, and white skin to black White skin on the black animal is completely pigmented in sixty to one hundred and twenty-nine days Hair color remains unchanged up to five months despite a change in the color of the skin Pigmentation of the white skin surrounding a black graft likewise occurs

The chief clinical interest in homotransplantation is as a life-saving measure in badly debilitated patients with extensive burns The homografts are used as a temporary skin dressing until the patient's condition warrants the use of autografts<sup>19</sup> This method of homotransplantation has been successfully used for large granulating wounds in a badly debilitated burned patient Skin was removed from a cadaver six hours after death and applied to the recipient seven hours later The cadaver had been refrigerated and was cold when the grafts were taken The grafts were wrapped in a moist sponge and left refrigerated until used<sup>68</sup> The three-month survival period of these grafts is one of the longest on record Unfortunate false publicity has led to the useless taking of skin from donors, who are led to believe that their skin will survive permanently Skin banks have even been proposed The occasions when homotransplants are indicated are very rare

### TRANSPLANTATION OF FLAPS

The transplantation of flaps is one of the oldest of all surgical technics Plastic surgery can thus claim its origin centuries before the Christian Era War injuries, accidents and punishments and the ever-present congenital deformities have always provided a stimulus for the development of reparative surgery Both Davis<sup>69</sup> and Koch<sup>15</sup> have reviewed the early history of skin transplantation and paid tribute to those who paved the way to modern plastic surgery According to Davis, the Hindus (750 to 800 B C) were the earliest recorded practitioners of real plastic surgery They understood the local shifting of skin flaps or sliding flaps that later somehow became known as the French method Other technics, such as the repair of a nose with a forehead flap, were developed by members of the lower castes in India who in-

technics in skin grafting should make possible the prompt healing of burns, the immediate closure of most traumatic or surgical wounds and the early repair of deforming scars and chronic ulcerations.

In 1943 Sano<sup>42</sup> described a method of adhesive fixation of skin grafts to a raw surface. By mixture of a specially prepared plasma solution with leukocyte extract a fibrinous adhesive coagulum is formed that eliminates the need for a dressing or suturing the graft. The leukocyte extract is "painted" on the graft, and the plasma solution on the recipient surface before the graft is applied.

Several other methods of fixation of skin grafts and for "gluing" severed nerves were suggested, and there are still occasional reports of the value of these methods.<sup>43, 44</sup>

Young<sup>45</sup> reports fibrin fixation of skin grafts by the addition of thrombin to the recipient area and plasma to the graft. A clot forms when the two are brought in contact. He concludes that the method has value in applying grafts to fresh surgical wounds, for holding grafts while compression dressings are being applied, and as a means of holding small grafts that are not to be held with a dressing. He does not recommend the use of fibrin fixation for granulating wounds.

Brown<sup>46</sup> cites his use of coagulum fixation of skin grafts to a granulating surface. In each case a graft without adhesive substance was applied as a control. None of these grafts were sutured in place, and there was a complete take of all the grafts, including the controls. Brown reports the observation of many surgeons performing skin grafts to granulating surfaces that spontaneous adhesion occurs if the graft is pressed against the raw surface for a few minutes.

An interesting suggestion explaining the value of adhesive methods in skin grafting has come from Medawar.<sup>47</sup> He points out that the lower the temperature the less enzymic autolysis occurs and the less the risk of loss of the dormant graft from infection. Fixation with bulky pressure dressings tends to keep the graft at a higher temperature and increases this danger. The adhesive method, without a dressing, allows the graft to remain at a lower temperature and favors its survival. This technic of open grafting was used successfully for many years by Porter and Greenough at the Massachusetts General Hospital, without, however, adhesive fixation of the grafts.

#### FULL THICKNESS GRAFTS

Wolfe-Krause or full thickness grafts, consisting, as the name implies, of the epidermis and full thickness of the dermis, have several advantages over grafts of intermediate thickness. One of the clearest and most complete expositions of the value of and indications for the full thickness skin graft has been presented by Byars.<sup>48</sup> Two important advantages of these grafts are emphasized the

minimal tendency to contract and wrinkle, and better color and texture of the surface. Full thickness grafts are harder to prepare and tedious to apply. They are more liable to failure, and the amount that can be transplanted is limited. The donor site must often be closed with a split skin graft. The advantages of these grafts are the reasons for their use.

Flexion is the functional motion of the hand so that little active stretching of the palmar skin occurs. Skin resurfacing of the palm is thus often best done with a full thickness graft that shrinks little. The same principle may apply in the definitive release of contracting scars of the neck. On the face there are delicate motions of expression, and the skin is exposed, so that both functionally and cosmetically the full thickness graft is preferred.

Full thickness grafts are usually taken from the groin, inner surface of the upper arm or abdominal wall. Skin from the fold behind the ear is available in small amounts and usually matches the skin of the face. Skin from the upper eyelid has been used by Wheeler<sup>49</sup> for repairs of the lids. A recent suggestion by Brown and Cannon<sup>50</sup> of full thickness grafts from the base of the neck has proved valuable because the grafted skin matches that of the face well, it is available in large amounts, and its function in kinetic areas of the face cannot be distinguished from the normal. An explanation for this observation is that only in the neck is there skin whose normal environment overlying the platysma muscle is similar functionally to the skin of the face, beneath which lie the delicate muscles of expression. In resurfacing the dorsum of the fingers to prepare for definitive tendon surgery, this graft has been used because of the loose areolar tissue beneath it in which the tendon will glide.

If a graft on the face fails to match the color of the adjacent skin, the color can be changed by permanent pigment injection, the same method used in tattooing. This technic of skin pigmentation was first described by Hance<sup>51</sup> and Byars.<sup>52</sup> It is not only of value in tinting grafts but also in masking the redness of capillary hemangioma or port-wine stain.<sup>53, 54</sup> The mixed pigments in the form of a thin paste are imbedded in the dermis by multiple puncture using fine cambric needles. The puncture is done either by hand or by a vibrating device.

Brown and Cannon<sup>55</sup> have described the composite graft from the ear for alar and columellar repairs. The graft, which comprises two layers of skin with the cartilage between, makes possible tissue replacement about the nostrils in a single operation. Minimal deformity of the ear, which can be repaired with local tissue, results. Dupertuis<sup>56</sup> has independently used segments of the ear lobe for similar repairs, particularly on the tip of

narrow pedicle containing only the coronary artery and vein that encircle the lip. Rotation of the flap through 180° is possible. Its greatest usefulness is in direct closure after excision of the lip for cancer and in secondary repairs for harelip or trauma.<sup>95-97</sup>

Brown and his associates<sup>12, 13</sup> have emphasized the value of more direct methods in the transfer of flaps in preference to the slower delaying and tubing technics. By providing an adequately broad base with a short pedicle the viability of the flap is assured. The flap can be accurately prepared to fit the defect resultant from trauma or surgical excision of scars and attached at the same time. This direct transfer may save many weeks or even months of hospitalization and disability. This method has proved of value not only for the upper extremity but also, surprisingly enough, for the lower extremity. Either the thigh or the calf can be the source of these flaps for the opposite leg if local flaps are inadequate.

For more extensive resurfacing of the lower extremity or other parts, open jump flaps from the abdominal wall carried on the forearm have been described.<sup>98, 99</sup> Edwards<sup>100</sup> has compared the experience in 26 cases of open jump flap with a similar series using tubed flaps also carried on the forearm. The 26 jump flaps took an average of one hundred and six days and six operations to complete, and none were lost. Thirty-five tubed flaps were started, and 9 failed, so that only 26 were completed. An average of three hundred and thirty-three days and ten operations were necessary for the repair.

The application of the principles of plastic surgery to problems of general surgery is well demonstrated in the recent articles on decubitus ulcers in paraplegia and in repairs of the chest wall following very radical surgery.

Barker<sup>101</sup> reports that excision and suture or the advancing of flaps has proved satisfactory in the closure of decubitus ulcers. Grafts are reserved for patients whose condition does not warrant the use of flaps. Gibbon and Freeman<sup>102</sup> report experience with 65 patients with decubitus ulcers treated by excision and closure by advancing local skin flaps. White and Hamm<sup>103</sup> describe 14 cases of decubitus ulcers in patients with spinal paraplegia in which repair was accomplished by the rotation of local flaps. A trend toward the use of rotated flaps rather than advancing of flaps through stellate incisions is noted in the more recent writings. This is emphasized by Conway,<sup>104</sup> who says "large ulcers are closed successfully in the highest percentage of cases when a flap of skin and subcutaneous tissue is rotated from an adjacent area and the defect at the site of procurement of the flap surfaced by a free graft of skin." The important additional factor in success of removing all bony prominence is stressed by Kostrubala.<sup>105</sup> I have found this to be true in my experience with decubitus

ulcers and in several cases have excised the outer table of the sacrum, removing with the bone all avascular and necrotic ligamentous and fascial tissue and leaving a base of healthy cancellous bone.

Both Maier<sup>106</sup> and Pickrell<sup>107, 108</sup> have reported the use of rotated flaps from the thoracic or abdominal wall and the skin of the breast and, in Pickrell's report, the use of free skin graft on the pericardium, for repairs of large defects of the chest wall following radical resection of tumors, resection of areas of radiation necrosis and in repairs following trauma.

## SUMMARY

An attempt is made to review early and recent developments that have led to present understanding of skin transplantation. Some of the principles of repair that have evolved with the perfection of methods and technics are presented. In the future, the development of direct methods and a more widespread understanding of basic principles throughout the surgical profession can be expected. Studies in wound healing and homotransplantation may cast further light on these puzzling problems.

herited surgical practice when it came to be thought unclean. Today the use of a flap of forehead skin for nasal reconstruction is spoken of as the Indian method. This method was brought to the United States by Warren<sup>70</sup> after a sojourn in Europe and described by him in 1837. Another important method of nasal reconstruction, using a flap from the upper arm, has come to use from the writings of Taliacotius<sup>71</sup> of Bologna, whose face is engraved on the certificate of the American Board of Plastic Surgery. In 1840 Warren<sup>72</sup> again wrote about nasal reconstruction. He pointed out the value of this flap in avoiding a deforming scar of the forehead. Today, this type of nasal reconstruction is known as the Italian method.

The tubing of a flap as a preliminary to its transfer was reported independently by Gillies<sup>73</sup> and Filatoff,<sup>74</sup> but Gillies was its greatest proponent. Through his writings and his disciples, who carried his teachings to many parts of the world, the method gained widespread recognition and popularity. For the first time multiple-stage migration of flaps to remote parts of the body was possible. The skin surface remained closed at all times, and the hazard of infection and thrombosis was reduced.

Webster,<sup>75</sup> in 1937, described the thoracoepigastric tubed pedicle flap, which utilized for blood supply the long thoracic, the superficial thoracic and the superficial epigastric arteries and thoracoepigastric veins. These vessels lie subcutaneously on the abdominal and chest walls and are thus included within the substance of the flap. Large flaps of this type have proved useful for many types of surgical repair on many parts of the body.

That the use of tubed pedicle flaps is not without hazards, however, is indicated by Macomber and Rubin,<sup>76</sup> who list the precautions in the preparation of tubed flaps and the complications that may arise in their preparation, delay and transfer. These include necrosis from tension or from excessive length, hemorrhage within the tube, infection, improper timing of delays, kinking or angulation of the tube, use of an inadequate flap and improper closure following delays and several others. This report is based on a series of over 300 cases of tubed flaps prepared for repairing complicated war wounds of the extremities.

To reduce the possible complications in the preparation of tubed flaps, Shaw and Payne<sup>77</sup> have found it advantageous in applying small flaps to the hand to tube the pedicle at the same time. This method combines the speed of the abdominal flap with the cleanliness of the tube. Macomber and his associates<sup>78, 79</sup> have re-emphasized the value of a skin graft in the bed from which a tubed flap is prepared as a means of primary wound closure. The free skin graft is also useful in closing the donor area and undersurface of large direct abdominal flaps.

The forehead flap, or Indian method, has found increasing usefulness today in the repair of surgical and traumatic cases not only of the nose<sup>80</sup> but also of other parts of the face (eyelid, lip, mouth, orbit, cheek and chin). Blair et al.<sup>81</sup> report from a wide experience with this type of flap in repairs of the face following radical surgery for cancer. The authors describe the methods used, and the principles underlying their use are illustrated in detail. Various descriptions of flaps for facial repairs have been presented by other authors.<sup>82-85</sup> The major disadvantage of the forehead flap is the deformity that results. Since a normal feature is destroyed, this flap should be avoided in young people. In a large Army plastic center, the arm flap, or Italian method, was used almost exclusively in nose reconstruction for this reason.<sup>86</sup>

New<sup>87</sup> has described the "sickle flap" as a method that minimized the deformity. The skin for the repair is taken high in the temple along the hairline. The flap is carried on a sickle-shaped pedicle extending upward along the temporal artery and lying completely within the hairline. Very large repairs are possible by this method, including the nose, lip, eyelid or cheek.

Kazanjan<sup>88</sup> has described the "median forehead flap," which is elevated from the midline of the forehead and carried on a pedicle between the brows. The vertical scar in the forehead is not deforming. A surprising amount of skin can be mobilized by this method, which can be used in repairs of the eyelid, nose or upper lip.

The "island flap," devised by Gursnay in 1887 and later presented by Monks<sup>89</sup> in 1898, also leaves no deforming scars. Only two vessels, branches of the temporal artery and vein, form the pedicle of the flap, which can be either hairless forehead skin or hair-bearing scalp. The vessels are identified by palpation and dissected free through an overlying linear incision. The mobilized flap and vessels are passed through a tunnel to the recipient area. This flap is most useful for the eyelids and brow.

Large flaps from the anterior portion of the neck and chest wall are also used in facial repairs to avoid any additional deforming scars of the face. These methods have been described and utilized by many authors.<sup>90-92</sup> Flaps from the neck have the additional advantage of matching facial skin in color and texture. Brown and Cannon<sup>93</sup> describe a large flap with the base above the clavicle that lies vertically down the chest or crosses to the opposite side above the nipple level. This flap provides a method of obtaining large amounts of skin for the face without the need of migration in multiple stages.

A very useful direct method for repairs about the mouth is the vermilion-bordered lip flap, originally described by Estlander<sup>94</sup> in 1872. This flap, comprising the full thickness of the lip, is carried on a

### CASE 34381

#### PRESENTATION OF CASE

A seven-year-old girl was admitted to the hospital because of pain and swelling of the left ankle.

The mother dated the illness back four months at which time the girl struck her left ankle and subsequently developed a slight limp. Four months before admission swelling was noted for the first time, and the ankle became painful. The pain gradually became more severe. Three months before admission the patient was said to have been feverish, although the temperature was not taken. X-ray films were taken by a physician, who made a diagnosis of Brodie's abscess.

On examination there was marked dental caries. There were bilateral palpable shotty inguinal nodes which were not tender. There was a 5-cm by 7-cm, firm, slightly tender swelling of the anterior medial aspect of the left ankle that seemed contiguous with the lower end of the tibia and did not appear to cross the ankle joint. The foot was held in valgus position, although flexion and extension were normal as compared to the opposite side. The left medial malleolus was lower than the right. Measurements from the midpatella to the medial malleolus were, on the right,  $9\frac{3}{8}$  and, on the left,  $9\frac{7}{8}$  inches. The circumference of the leg, measured 1 inch above the medial malleolus, was right,  $6\frac{1}{2}$  and left, 7 inches. There was no remarkable redness or increased heat. There was no bruit. The temperature was normal.

Laboratory examination revealed a normal urine, a hemoglobin of 11.8 gm, a white-cell count of 8200 and a normal differential. The blood calcium was 8.8 mg per 100 cc, the phosphorus 5.3 mg per 100 cc, and the alkaline phosphatase 5.5 units per 100 cc. The total protein was 6.7 gm per 100 cc. The sedimentation rate was 16 mm in 1 hour. The blood Hinton and tuberculin tests were negative.

An x-ray film showed a rarefied area within the cancellous portion of the distal end of the tibial epiphysis, more toward the medial side (Fig 1). The rarefaction extended to the metaphysis and also seemed to involve the cortex of the bone in one

area. There was some suggestion of local decalcification within the adjoining epiphysis. Soft-tissue swelling was present, and there was some periosteal new-bone formation along the medial aspect of the distal tibia. There were no lesions in the spine,

FIGURE 1

pelvis, skull or lungs. Measurement of teleroentgenograms showed  $\frac{1}{4}$ -inch lengthening of the left tibia.

On the seventh hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. CHANNING C. SIMMONS: According to the x-ray films this patient has an area of bone destruction with slight periosteal proliferation in the lower end of the left tibia. It can be noticed that this tibia is slightly larger than the other. It is a question whether the lesion extends across the epiphysis or whether the appearance in the film is due to rarefaction of disuse. The lymph node in the groin, I think, is of very little significance.

Diagnosis of these bone tumors, as I have said many times, lies between a diffuse skeletal disease, an inflammatory condition, and some form of tumor. From the data at hand, I think we can fairly well rule out a general skeletal disease. Inflammatory conditions such as syphilis, tuberculosis and osteomyelitis are all possibilities. The blood Hinton

The temperature and pulse were normal

Laboratory examination revealed a normal urinalysis. The clotting time varied between 20 seconds and 2 minutes and 5 seconds. A bilateral lumbar sympathectomy was done, and communicating leg veins were ligated.

*Second admission* (three months later) Following the operation the patient did well until she developed an acute maxillary sinusitis. She noticed some painless swelling of both lower extremities at this time. Three days after the onset of the sinusitis she noted left-sided back pain on breathing. She developed a cough, fever and bloody sputum. On readmission to the hospital the chest findings, including x-ray examinations, were consistent with pulmonary infarction. The clotting time was 5 minutes, and the prothrombin time 27 seconds (normal, 22 seconds). Venograms showed no filling of the deep veins in either leg. A ligation of the inferior vena cava in continuity was done.

*Third admission* (two years and five months later) Following the vena-cava ligation the patient had bilateral varicose ulcers, which kept breaking down. A bilateral femoral-vein ligation was done at this time, and a dilatation and curettage were performed. x-ray treatment (1000r) was given to stop menstrual bleeding.

*Fourth admission* (fourteen months later) In the interval the patient's condition was unchanged, and the leg ulcers continued to break down if the patient walked excessively. Three months before admission the patient developed shingles around the buttocks. This subsided but six weeks before admission an abscess the size of a billiard ball developed over the lower spine. This broke spontaneously and subsided.

On examination there were moderate external hemorrhoids, but there was no pilonidal dimple. A hemorrhoidectomy was done.

*Fifth admission* (one and a half years later) Ten days before admission the patient noticed a steady gnawing pain under the tip of the xiphoid. This persisted and became more severe and shifted to below the original site. The pain was aggravated by movement and only partially alleviated by rest and medication. The pain radiated to the upper lumbar region and back. There was no nausea, vomiting or anorexia. The bowel movements were regular, and there was no melena. There were no chills, no fever and no bouts of crampy pain. There was no weakness or weight loss.

On examination there was some vague, not localized, slight abdominal tenderness.

The blood pressure was 116 systolic, 70 diastolic. Examination of the blood disclosed a white-cell count of 14 200, with 81 per cent neutrophils. The platelets were somewhat decreased. The serum amylase was 13 units, and the prothrombin time was 18 seconds (normal, 16 seconds). The specific gravity of the urine was 1.012. There was a + test for albumin and the sediment contained an occasional red cell and 25 white cells per high-power field. The stool was guaiac negative.

The pain was much relieved by the third hospital day, and the patient was taking fluids comfortably. A gastrointestinal series, Graham test and barium enema were negative.

During the evening of the fourth day there was an exacerbation of pain with vomiting of recently ingested water. Abdominal tenderness was not well localized to either side of the abdomen. There was no spasm or distention. The vomiting continued, and the maximum pain and tenderness shifted to the right, chiefly in the upper quadrant. There was a sense of resistance to palpation on the right. The temperature was normal. The abdomen was quiet on auscultation, and an occasional normal peristaltic sound was heard. There was no change in the sound with exacerbations of pain. On the fifth hospital day severe pain, nausea and vomiting recurred and persisted, and the tenderness was constantly referred to the right lower quadrant.

An operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR ARTHUR W ALLEN Have you some films of the abdomen? May we see them now?

DR JAMES J MCCORT Do you want to see the early films of the infarct?

DR ALLEN I do not know that we need to. I am more interested in the films of the present illness. You probably have a plain film of the abdomen taken shortly after admission.

DR MCCORT No, we do not have that. These films you see are of the gall bladder on the last admission, and the gall bladder is seen to concentrate the dye well. No calculi are present. This is the barium enema. There is no definite abnormality demonstrated in the large bowel. There is only slight filling of the terminal ileum on this examination. There are no defects, and no evidence of

test was negative, which pretty well rules out syphilis, although bone syphilis might give a negative Hinton test. An inflammatory condition has to be considered — a Brodie's abscess, so-called, or localized osteomyelitis. We have to consider osteogenic sarcoma, Ewing's sarcoma, plasma-cell myeloma, eosinophilic granuloma and giant-cell tumor.

An inflammatory condition in a child usually is found in the epiphyseal region, which is stimulated, causing the bone to grow longer as in this case. Whether tumor in the same situation will do this, I do not know. However, the normal temperature militates against an inflammatory condition. Of the tumors, osteogenic sarcoma may be present. It is rarely found in this position or gives this picture, although osteogenic sarcoma can simulate any condition. Giant-cell tumor gives a picture of bone destruction without new-bone formation, but there was new-bone formation associated with this lesion. Eosinophilic granuloma I should not consider. Plasma-cell myeloma is usually a multiple disease, although single bones are occasionally involved. Ewing's sarcoma may perfectly well give this picture of destruction but usually with much more tumor clinically than is suggested by the x-ray film. In other words, the whole leg is enlarged. Ewing's sarcoma may give a little fever or a slightly elevated white-cell count.

I think, frankly, that it is impossible to make a diagnosis. It would lie between an early giant-cell tumor and an inflammatory condition, such as Brodie's abscess. The only way to make a diagnosis definitely in this case would be to do a biopsy and let the treatment be governed by what was found. Whether or not it would be possible to do a suction aspiration biopsy, I do not know.

DR STANLEY M. WYMAN: From the radiologist's point of view, everything Dr. Simmons has said is entirely correct. My own feeling about it is that the chief thing to decide is whether the lesion is inflammatory or neoplastic, and if neoplastic, whether it is benign or malignant. In favor of infection are the soft-tissue swelling, the elongation of the bone, the periosteal reaction and the circumscription of the lesion without any perceptible or gross reaction about the lesion. I think I should place inflammation of low grade as my first bet.

DR BENJAMIN CASTLEMAN: Are there any other suggestions?

A PHYSICIAN: How often does a giant-cell tumor occur in this age group?

DR CASTLEMAN: According to Jaffe\* one does not see it before twenty.

DR LAURYNCE L. ROBBINS: Oh, yes you do, I have seen it in patients around fourteen.

DR CASTLEMAN: I do not believe I have seen one in a child of seven.

\*Jaffe H. L., Lichtenstein L. and Porus R. B. Giant cell tumor of bone: its pathologic appearance, grading, supposed variants and treatment. *Arch. Path.* 30:993-1031, 1940.

DR ROBBINS: We do not see them until the epiphysis is closed because they are usually in the epiphysis.

#### CLINICAL DIAGNOSIS

Bone sarcoma?  
Brodie's abscess?

#### DR SIMMONS'S DIAGNOSIS

Benign giant-cell tumor?  
Brodie's abscess?

#### ANATOMICAL DIAGNOSIS

*Brodie's abscess of tibia*

#### PATHOLOGICAL DISCUSSION

DR CASTLEMAN: At operation the surgeon exposed a trap door in the cortex and curetted some material that appeared grossly to be chronic inflammatory tissue. On microscopical examination we found an exudate of polymorphonuclears, lymphocytes, monocytes and plasma cells that would fit in with a Brodie's abscess. Culture showed *Staphylococcus albus*. The patient is doing well.

DR SIMMONS: What was the preoperative diagnosis in the ward?

DR CASTLEMAN: It varied. Everyone who examined her had a different diagnosis. On the anesthesia sheet the preoperative diagnosis was given as sarcoma of the lower tibia, but several members of the orthopedic staff said it was a Brodie's abscess. Neurofibroma was also suggested because the leg was longer on one side.

#### CASE 34382

##### PRESENTATION OF CASE

*First admission.* A forty-year-old woman was admitted to the hospital because of persistent phlebitis and ulcers on the lower legs. The phlebitis had commenced twenty-five years previously following an appendectomy, had recurred following childbirth eleven years later, and a bilateral high saphenous ligation was done after another five years. Seven years before entry, again following childbirth, there was an attack of phlebitis of the right arm. The legs were not involved. Since then there were recurring ulcers on the lower legs. One year before entry because of swelling around the hips, thrombosis of the pelvic vein was diagnosed.

The patient was well developed and well nourished. Examination of the heart, lungs and abdomen was negative. There was no edema of the legs although they appeared swollen and the skin was tense. There was no palpable arterial pulsation below the femoral veins. There were ulcers on the medial aspect of both legs, around and above the malleoli.

thrombin level at the time of the second admission was 27 seconds, with a normal of 22 seconds, and on the last admission it was still a little higher than normal, 18 seconds. It is a fairly well understood fact throughout the country that we do not often have thrombophlebitis or thrombosis of blood vessels occur in persons who have a higher than normal prothrombin time. In the original studies of Bancroft et al\* on postoperative thrombophlebitis, all the patients who developed this complication had a lower than normal prothrombin time in the series of patients studied by him and his co-workers. We have plenty of cases here of patients who have had infarcts following treatment by anticoagulants with a prothrombin level above normal, although it is not common and we do not expect it.

The character of this woman's pain is interesting, and the onset is described as being fairly sharp and fairly sudden, but it does not give the impression of the onset of mesenteric thrombosis. There are at least two types of thrombosis with which I am familiar: thrombosis of the mesenteric artery and thrombosis of the venous system, which produce very different pictures. When the mesenteric thrombosis involves the arterial system, the pain is more excruciating than it is in almost any other disease. These patients are precipitated into shock from this pain. They have a weak pulse, and are grav, restless and sweating, and most patients who develop that difficulty are in the arteriosclerotic age group, and they are in a pretty hopeless state usually when they enter the hospital. In this type of thrombosis of the mesenteric vessels one almost invariably finds a high white-cell count. That is one of the helpful differential diagnostic points. It is not at all uncommon to find a count well into the forty thousands. Also this condition is progressive, although one may rarely find a favorable situation and a satisfactory outcome following resection of the involved small intestine. The mortality in this disease is extremely high.

In venous thrombosis, however, the onset is a little more insidious and is apt not to give as high a white-cell count, but even in that situation the patient should not be completely afebrile and in as good condition as this patient apparently was. It is possible for a venous thrombosis of the mesentery to carry on over a period of days as this patient did prior to the time that operation seemed indi-

cated. I am inclined to think, having tried my best to pin this on some thrombotic mechanism of the vascular system within the abdomen, that perhaps it was not present in this case — that this woman had something else to account for her symptoms.

The commonest cause of epigastric distress, followed by nausea and vomiting, and pain settling in the right lower quadrant, is acute appendicitis. There are some features of the story that make one wonder if that was not really the cause of this disturbance. She had the proper white-cell count, the proper ratio of polymorphonuclear cells, and the only out about it, which might not be an out at all, is the apparent relief of pain on the third hospital day, with a recurrence twenty-four hours later. The fact that she was afebrile and had a normal pulse and so forth is somewhat in favor of some other very mild inflammatory affair or some mechanical effect. The reason I was interested in these shadows — you may not see them but they are present in the first films — is that I thought they could be in the course of the ureter. It is not too uncommon to have a Dietl's crisis mimic other situations in the abdomen. We recently had a patient sent into the hospital with what appeared to be full-blown acute intestinal obstruction. A plain film of the abdomen, instead of showing dilated gas-filled loops of bowel as suspected, showed a great many stones in the right kidney pelvis, with one or two down the course of the ureter. The urologist helped us out and passed the catheter up the patient's ureter and dislodged the stones and the symptoms of intestinal obstruction were immediately relieved. So it is possible that this woman under discussion could have had a ureteral stone.

Our attention is called to this spot in the ileum that looks atypical. We are carefully told in the history that this is not intestinal obstruction from the character of the peristaltic sounds heard through the stethoscope. I will be surprised if it turned out to be the site of this patient's difficulty, since I would not expect to find barium passing through the area so readily, also I believe the symptomatology would be different. It is obvious that the woman did not have intussusception. Intussusception of the small bowel is common enough, but it gives perfectly typical symptoms of small-bowel obstruction, which I am sure this woman did not have. Because an operation was performed — and I do not know whether anyone would consider cystoscopy an operation or not — I suppose that this

dilated loops of small bowel, although some loops contain air

DR ALLEN There is a small shadow to the right of the spinal column. Does that have any significance at all?

DR McCORT I do not know the significance of the small calcification in the right lower quadrant.

DR ALLEN Is it anywhere near the course of the ureter?

DR McCORT It seems a little bit lateral. I cannot rule out a ureteral calculus without a urogram, but it may be a calcification in a mesenteric lymph node.

The films of the gastrointestinal tract were taken at the time the barium was ingested, and no abnormality is demonstrated in the stomach or duodenum. This film was taken six hours after the barium was administered, and the stomach is completely empty. The greater portion of the barium is present in the lower small bowel and ascending colon. A narrowed area, several centimeters in length, is present in the terminal ileum. This might bear further investigation to determine whether it is a tumor or inflammatory stricture.

DR ALLEN Is that in the ileum?

DR McCORT Yes.

DR ALLEN This patient is interesting from many points of view, and since I have no clear-cut idea as to what brought her in here the last time, I think I am justified in reviewing some of the points of the past history. In the first place it appears that this woman developed her original thrombophlebitis at the age of fifteen. This is unusual because although we do see this complication following injuries to the lower extremities in young people, such as burns and fractures, it is rare to have it occur as a complication of an appendectomy or any such operation as that. Without a doubt she had a rather fulminating attack of bilateral femoral phlebitis at that time. It is common to have in these patients a recurrence of their thrombophlebitis following childbirth or operation, and she proceeded to behave in this characteristic fashion. The story brings out a good many of the methods of examination and treatment of chronic thrombophlebitis that we used in previous years but now are not using at all. For instance, before this woman had an interruption of the femoral vein, she had phlebograms made of the venous system. That was thought to be quite important at one time in this hospital. It is rarely, if ever, thought necessary now.

DR BENJAMIN CASTLEMAN It was done in 1943.

DR ALLEN Another point is that she had an operation devised by Dr Linton several years ago of interruption of the communicating veins between the superficial and deep systems. This was preceded by a lumbar sympathectomy, probably done because she was said to have some difficulty with her arterial circulation as well, since it is recorded that no pulsations in the arteries were felt below the femoral veins. This operation of interruption of communicating veins between the superficial and deep systems has been fairly well abandoned now for a better procedure, which consists of stripping out the superficial system, the long saphenous and short saphenous veins if necessary, and interruption of the superficial femoral vein just below the profunda. These procedures are more apt to succeed in preventing recurrent illnesses from the lymphedema and ulceration that is so common as an aftermath of deep thrombophlebitis.

There is nothing much to say about some of these previous admissions other than what I have brought out, except that I should emphasize that we have done in this hospital very few interruptions of the vena cava. We have felt that many of the patients that might be subjected to this form of treatment actually do better with a procedure of less magnitude, that is, bilateral interruption of the femoral veins with removal of the thrombi, if present, and treatment with anticoagulants afterward. I think somewhere in the neighborhood of fifteen vena cava interruptions only have been done here during the time when we have had approximately 3000 patients under treatment, either prophylactically or therapeutically, for thrombophlebitis and pulmonary embolism. Interruption of the vena cava should be reserved, we believe, for those patients who are having septic infarcts arising from the pelvic veins. It is wise to interrupt also the ovarian or spermatic vein, as the case may be, provided these veins are also thrombosed. Although vena-cava interruption is a safe operation so far as life and death are concerned, it leaves these patients, as a rule, more handicapped than some of the less radical procedures that we have used.

Coming down to the final admission, the fifth admission, which is the present illness, it would be a natural supposition that the abdominal discomfort that this patient had might in some way be associated with her great tendency to thrombose her blood vessels. It is interesting that the pro-

thrombin level at the time of the second admission was 27 seconds, with a normal of 22 seconds, and on the last admission it was still a little higher than normal, 18 seconds. It is a fairly well understood fact throughout the country that we do not often have thrombophlebitis or thrombosis of blood vessels occur in persons who have a higher than normal prothrombin time. In the original studies of Bancroft et al\* on postoperative thrombophlebitis, all the patients who developed this complication had a lower than normal prothrombin time in the series of patients studied by him and his co-workers. We have plenty of cases here of patients who have had infarcts following treatment by anticoagulants with a prothrombin level above normal, although it is not common and we do not expect it.

The character of this woman's pain is interesting, and the onset is described as being fairly sharp and fairly sudden, but it does not give the impression of the onset of mesenteric thrombosis. There are at least two types of thrombosis with which I am familiar: thrombosis of the mesenteric artery and thrombosis of the venous system, which produce very different pictures. When the mesenteric thrombosis involves the arterial system, the pain is more excruciating than it is in almost any other disease. These patients are precipitated into shock from this pain. They have a weak pulse, and are gray, restless and sweating, and most patients who develop that difficulty are in the arteriosclerotic age group, and they are in a pretty hopeless state usually when they enter the hospital. In this type of thrombosis of the mesenteric vessels one almost invariably finds a high white-cell count. That is one of the helpful differential diagnostic points. It is not at all uncommon to find a count well into the forty thousands. Also this condition is progressive, although one may rarely find a favorable situation and a satisfactory outcome following resection of the involved small intestine. The mortality in this disease is extremely high.

In venous thrombosis, however, the onset is a little more insidious and is apt not to give as high a white-cell count, but even in that situation the patient should not be completely afebrile and in as good condition as this patient apparently was. It is possible for a venous thrombosis of the mesentery to carry on over a period of days as this patient did prior to the time that operation seemed indi-

cated. I am inclined to think, having tried my best to pin this on some thrombotic mechanism of the vascular system within the abdomen, that perhaps it was not present in this case — that this woman had something else to account for her symptoms.

The commonest cause of epigastric distress, followed by nausea and vomiting, and pain settling in the right lower quadrant, is acute appendicitis. DR ALLEN Is that in the ileum?

DR McCORT Yes

DR ALLEN This patient is interesting from many points of view, and since I have no clear-cut idea as to what brought her in here the last time, I think I am justified in reviewing some of the points of the past history In the first place it appears that this woman developed her original thrombophlebitis at the age of fifteen This is unusual because although we do see this complication following injuries to the lower extremities in young people, such as burns and fractures, it is rare to have it occur as a complication of an appendectomy or any such operation as that Without a doubt she had a rather fulminating attack of bilateral femoral phlebitis at that time It is common to have in these patients a recurrence of their thrombophlebitis following childbirth or operation, and she proceeded to behave in this characteristic fashion The story brings out a good many of the methods of examination and treatment of chronic thrombophlebitis that we used in previous years but now are not using at all For instance, before this woman had an interruption of the femoral vein, she had phlebograms made of the venous system That was thought to be quite important at one time in this hospital It is rarely, if ever, thought necessary now

DR BENJAMIN CASTLEMAN It was done in 1943

DR ALLEN Another point is that she had an operation devised by Dr Linton several years ago of interruption of the communicating veins between the superficial and deep systems This was preceded by a lumbar sympathectomy, probably done because she was said to have some difficulty with her arterial circulation as well, since it is recorded that no pulsations in the arteries were felt below the femoral veins This operation of interruption of communicating veins between the superficial and deep systems has been fairly well abandoned now for a better procedure, which consists of stripping out the superficial system, the long saphenous and short saphenous veins if necessary, and interruption of the superficial femoral vein just below the profunda These procedures are more apt to succeed in preventing recurrent illnesses from the lymphedema and ulceration that is so common as an aftermath of deep thrombophlebitis

There is nothing much to say about some of these previous admissions other than what I have brought out, except that I should emphasize that we have done in this hospital very few interruptions of the vena cava We have felt that many of the patients that might be subjected to this form of treatment actually do better with a procedure of less magnitude, that is, bilateral interruption of the femoral veins with removal of the thrombi, if present, and treatment with anticoagulants afterward I think somewhere in the neighborhood of fifteen vena cava interruptions only have been done here during the time when we have had approximately 3000 patients under treatment, either prophylactically or therapeutically, for thrombophlebitis and pulmonary embolism Interruption of the vena cava should be reserved, we believe, for those patients who are having septic infarcts arising from the pelvic veins It is wise to interrupt also the ovarian or spermatic vein, as the case may be, provided these veins are also thrombosed Although vena-cava interruption is a safe operation so far as life and death are concerned, it leaves these patients, as a rule, more handicapped than some of the less radical procedures that we have used

Coming down to the final admission, the fifth admission, which is the present illness, it would be a natural supposition that the abdominal discomfort that this patient had might in some way be associated with her great tendency to thrombose her blood vessels It is interesting that the pro-

## PHYSICIAN OF AYSGARTH

THE general practitioner, having suffered somewhat of an eclipse in the Age of Specialism, is returning to the favor that he merits. He has had special sections devoted to his calling in important medical associations, and an academy has been founded to which he may aspire. He has been the recipient of spontaneous tributes such as was accorded him by Miss Mary Ellen Chase in her address published in the *Journal* a month ago. Perhaps his next danger will be the risk of turning into that paradoxical paragon, the general specialist!

Miss Chase's tribute, however, was to a breed of physician somewhat more and somewhat less than the general practitioner. It was to the physicians who represent the essence of general practice—those rugged individualists, the country doctors

Of such basic fiber is Dr William N. Pickles, of Aysgarth, Yorkshire, whose Cutter Lecture on Preventive Medicine appears in this issue of the *Journal*. Dr Pickles also, in his life and his accomplishments, illustrates not so much the difference between the general practitioner and the specialist, as he does the advantages to be found in country practice over the limitations imposed by practice in the city.

This comparison is not a new one, and the idea is one to which many medical men take kindly, here as abroad. Physicians everywhere have been imbued with reverence for Withering and the Shropshire foxglove bells, and for Edward Jenner, who recorded the temperature of hibernating hedgehogs for John Hunter while mentally incubating his own great contribution to medicine. They remember with respect Crawford W. Long, of Georgia, and Ephraim McDowell, the backwoods ovariologist, and a host of other country doctors whose services have been equally faithful if less eventful.

Dr Pickles is a present example of one who has taken advantage of the peculiar opportunities afforded him as a country doctor to gather knowledge and to acquire wisdom and, by virtue of his intimate acquaintance with his people, to observe the character of disease and trace its spread through a familiarly known population.

Perhaps the secret of his success is best expressed by his own thoughts as he looked down upon his Yorkshire valley from an adjacent hilltop one summer evening:

Our attractive little lake seemed to lie at my feet, and one by one I made out most of our gray villages with their pall of smoke. And as I watched the evening train creeping up the valley, with its pauses at our three stations, I had this strange thought, that there was hardly a man, woman or child in all those villages of whom I did not know even the Christian name and with whom I was not on terms of friendship.

A graduate of London University in 1910 and a member of the Royal College of Physicians of London, Dr Pickles is a country practitioner and medical officer of health for the Aysgarth Rural District. He is the author of *Epidemiology in Country Practice*, published in 1939 and occupies the unique position for a rural health officer of being called

woman had a laparotomy, and my opinion is that acute appendicitis was probably the reason for the exploration

DR ALFRED KRANES Would the fact that the appendix was supposed to have been removed many years previously alter your opinion on that?

DR ALLEN Is it in the history? I read it and completely forgot it during my discussion of her interesting story

DR KRANES The appendix may still be there

DR ALLEN But probably not

DR CASTLEMAN Why not make another choice?

DR ALLEN I will come back to ureteral colic as a second choice

DR CASTLEMAN Dr Hardy, will you tell us what Dr Linton thought about this case?

DR IRAD B HARDY To bring you up to date briefly about the previous operation, it is of interest that following vena-cava ligation she did, as Dr Allen mentioned, have some disability in that prior to operation she had been quite a golfer and since the ligation she has never been able to make eighteen holes without fatigue Also of interest, since interruption of the femoral veins, the legs have been well That point did not seem clear in the record She had no further ulcerations for some time, and it does not appear that she will On admission to the hospital the idea was certainly in the back of Dr Linton's mind that the process in the abdomen might be another manifestation of venous thrombosis since she had shown such a tendency to it At about the time the gastrointestinal series was reported negative, it was realized that an intravenous pyelogram should precede everything and while planning that procedure, she began to get sicker and complained more of abdominal pain Finally on the fifth or sixth hospital day it appeared necessary to explore her as an emergency without the benefit of getting her more adequately prepared in the way of antibiotics or a Miller-Abbott tube However, a Levine tube was passed, and the patient was explored in the middle of the night

#### CLINICAL DIAGNOSIS

Mesenteric venous thrombosis?

DR ALLEN'S DIAGNOSIS

Ureteral stone

ANATOMICAL DIAGNOSIS

*Mesenteric venous thrombosis*

#### PATHOLOGICAL DISCUSSION

DR HARDY A loop of terminal ileum about a foot in length was found to be involved with venous mesenteric thrombosis, and the mesentery was involved over a great extent In doing the resection to remove all the obviously involved mesentery, it became questionable whether the blood supply to the right colon had not become jeopardized, so that resection of the terminal ileum plus a right colectomy and an ileotransverse colostomy were performed The patient did well for a few days after operation and then went into a peculiar state of peripheral vascular insufficiency with low blood pressure and cold and clammy upper extremities The legs remained dry and fairly warm The cause of the condition was uncertain There was no evidence of intraperitoneal irritation The heparin and penicillin she had been getting were omitted, and strangely enough her chart rapidly improved and she got out of the state of peripheral shock The temperature, which had risen to 104°F, and the pulse came down Since then she has rapidly improved and is doing very well now We are considering the possibility of trying heparin-sensitivity tests on her but not too soon The clotting time is being maintained at what we think is a satisfactory level We were interested to know whether it was possible for heparin, which she was getting, to play a part in the postoperative picture At the present time large maintenance doses of dicumarol are keeping the prothrombin time at a satisfactory level

DR CASTLEMAN The specimen received showed an adherent thrombus in the ileocolic vein and most of its tributaries There was infarction of all the terminal ileum, but microscopically the ascending colon was viable The ordinary example of mesenteric venous thrombosis involves the larger veins, such as the superior mesenteric The absence of involvement here of the larger veins might account for the minimal symptoms that she had before the final episode preoperatively I believe this is the first case I have seen in which there was spontaneous thrombosis of a vein smaller than the superior or inferior mesenteric I reviewed the sections of the femoral veins removed a couple of years ago, and they showed intimal sclerosis, there was also a little intimal sclerosis in the ileocolic vein I am still at a loss to explain this unusual condition

sion After the war he studied medicine, taking his degree at the University of Toronto. He served an internship in England, practiced general medicine in Canada and studied human relations at Yale, returning then to England to study psychiatry.

During the second World War he was appointed director-general of the Medical Services of the Canadian Army and helped to develop the Pulhems system for determining aptitudes. In November, 1944, he became Canada's first deputy minister of health in the newly organized Department of National Health and Welfare. Two years later he resigned this post to become executive secretary of the Interim Commission of the World Health Organization.

In 1945 Dr. Chisholm was cited in connection with the Albert A. and Mary Lasker Award for "safeguarding the mental health of Canadian soldiers as a psychiatrist, soldier, philosopher, and administrator."

Dr. Chisholm is to be congratulated on his election, our friends and neighbors across the border are to be congratulated on the selection of a native son for this eminent position.

## POSTGRADUATE MEDICAL EDUCATION IN CONNECTICUT

EXPANSION of facilities for postgraduate medical education in Connecticut was recently announced by President Seymour of Yale University. In co-operation with the Connecticut State Medical Society, the University is inaugurating a program to provide for short and long refresher courses for Connecticut physicians and to assist small hospitals in training resident physicians who are preparing for various medical specialties. Dr. William R. Willard, associate professor of public health, has been named assistant dean in charge of postgraduate medical education.

The expanded program is an extension of already successful co-operation between the University and the State Society that has made possible year-round operation of an institute of occupational medicine and hygiene, a joint endeavor with various state mental hospitals on the part of the Univer-

sity and the Clinical Congress of the Society, held at Yale each fall, which attracts from 600 to 800 physicians to its sessions. Like the Postgraduate Lecture Course of the Massachusetts Medical Society, the Connecticut program offers physicians an opportunity to keep abreast of the latest advances in therapy and public health. Members of the medical profession in Connecticut and elsewhere will watch the development of the program with great interest.

---

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### CHANGE IN RATE FOR CRIPPLED-CHILDREN CARE

On or after October 1, the all-inclusive per diem rate paid by the Department of Public Health to hospitals for care of crippled children will be increased to \$10.00. Until recently, when the Department of Public Health and the Department of Education were successful in increasing the amount, the rate paid had been \$8.00.

In the past year in an attempt to set a standard rate for payments based upon actual cost to hospitals for services given, a study was made by the Department of Public Health in conjunction with the Departments of Welfare, Mental Health, Correction and Education and with the Industrial Accident Board. A plan, satisfactory to the hospitals rendering the services and to the Commonwealth as a purchasing agent, was drawn up by an unpaid commission composed of the heads of the departments previously mentioned with the co-operation of the Veterans Administration. The plan was incorporated in Senate Bill 430 (1948), and was presented before the recent legislature. However, this bill was not passed.

The defeat of the bill left the Department of Public Health in the position of paying for hospital services of certain programs at a rate not only below posted hospital charges but also below actual costs to the hospitals. In the care of crippled children and rheumatic-fever patients the department has been limited in reimbursements to all-inclusive per diem rates of \$8.00. Reports from some hospitals of Greater Boston have shown that all-inclusive per diem cost for these patients approximates \$16.00. The result is that certain hospitals are subsidizing crippled-children programs to the extent of \$8.00 a day for each case.

The Department of Public Health hopes that this increase in rate will to some extent lighten the financial burden carried by the hospitals.

repeatedly in consultation by the principal health authorities in England and Scotland

In 1935 he lectured on "Epidemiology in Country Practice" before the Royal Society of Medicine, he gave the Milroy Lecture before the Royal College of Physicians in 1942 and the Finlayson Lecture of the University of Glasgow in 1946. He studied the incubation period of epidemic hepatitis years before epidemic hepatitis acquired its current importance, and was the first to recognize the presence of Bornholm disease in Great Britain, and to describe its clinical and epidemiologic behavior.

He has developed to a high degree the pastoral qualities of the physician, at the same time making so fruitful a study of rural epidemiology that his influence has spread over the United Kingdom. What more can be said of anyone than that he tilled well the soil whereon he was placed?

## BLUE SHIELD AND THE PREMATURE INFANT

ELSEWHERE in this issue of the *Journal* a Blue Shield release appears concerning the definition of obstetric services as they apply to the "routine" care of the premature infant. The point around which discussions may revolve is the statement that "during confinement of the mother, Blue Shield does not cover routine care rendered by other than the physician who accomplished the delivery." This statement implies that care of the premature infant may be a part of the routine care of the confinement and is not chargeable to Blue Shield as a legitimate added expense.

Criticism of the assumption that the care of a premature infant may in any case be routine has been the result, notably on the part of the *Norfolk Medical News*, which raises the question, in its issue of June 8, 1948, whether the care of the premature baby should ever be classified as other than a medical emergency. This classification was apparently so intended by the Massachusetts Department of Public Health when it sponsored Section 67A of Chapter 111 of the General Laws, providing for the reporting of the birth of a premature infant elsewhere than in a hospital and the transportation of such an infant to a hospital suitably equipped for its care.

The matter requires further clarification in order that the financial responsibility of Blue Shield may be fixed and criticism reduced to a minimum. Obviously an acceptable definition of prematurity should first be established, and weight is the simplest factor on which to base this classification. Five and a half pounds, or 2500 gm, has been used as such a standard, the incidence of births at this weight or less being from 5 to 6 per cent of the total. If 5 pounds is accepted as the standard the incidence is nearer 4 per cent. The group weighing from 5 to 5½ pounds and the group weighing less than 5 pounds at birth are approximately equal, with a very low mortality rate for the former. On this basis Massachusetts law defines prematurity as of 5 pounds or less and in New York, although 5½ pounds is accepted as the standard for prematurity, special care in premature centers is not offered unless the baby at birth weighs 4 pounds or less. The sound suggestion has been made that for Blue Shield purposes a birth weight of 4½ pounds or less be accepted as the criterion for prematurity.

Individual infants will vary greatly as to the amount of care required to start them safely on their way, but it should be accepted that the majority of premature infants as defined above will require special oversight and that only a very small minority, if any, should be considered as suitable candidates for the routine attention accorded the newborn. For practical purposes such care may be considered as part of the routine of an obstetric case only if it can be given safely by the physician who made the delivery, at the hospital where the delivery took place and then only during the period of confinement of the mother.

## DIRECTOR-GENERAL OF WORLD HEALTH ORGANIZATION

DR BROCK CHISHOLM, a Canadian, has been elected the first director-general of the World Health Organization, the *News Letter* of the Organization reports. Dr Chisholm, born in Oakville, Canada, in 1897, entered the Canadian Army during World War I as a private, later receiving a commis-

## BLUE CROSS - BLUE SHIELD

### OBSTETRIC COVERAGE

The Blue Shield subscriber certificate defines obstetric services in part as "routine care of a full term or premature newborn, including circumcision when undertaken during confinement of the mother and when provided by the physician who accomplished the delivery." In another section, routine care, including circumcision, of a full-term or premature newborn infant is excluded when undertaken during the confinement of the mother by any physician other than the one who accomplished its delivery. As applied to premature infants these provisions mean that

During confinement of the mother, Blue Shield does not cover routine care rendered by other than the physician who accomplished the delivery.

After confinement of the mother, Blue Shield covers routine care rendered by any participating physician.

During and after confinement of the mother, Blue Shield covers other than routine care rendered by any participating physician.

Experience with these provisions has demonstrated that the question of whether there is such a thing as routine care of a premature infant is essentially academic because, even with the exclusion of coverage during confinement of the mother, most premature infants remain in the hospital in excess of the maximum number of benefit days provided by Blue Shield.

### MISCELLANY

#### NEW FOUNDATION

The Arthritis and Rheumatism Foundation has been organized to promote a united nation-wide attack on arthritis and other rheumatic diseases according to a release from W. Paul Holbrook, M.D., Tucson, Arizona, its president. The new Foundation is sponsored by the American Rheumatism Association in co-operation with the National Arthritis Research Foundation, The Detroit Fund for Crippling Diseases, and others.

"The organization," the release continues, "has been created to unite the efforts of lay and medical leaders in developing a new voluntary health agency, comparable in the field of rheumatism, to such agencies as the National Tuberculosis Association, The National Foundation for Infantile Paralysis and the American Cancer Society."

Its main objectives include the making of a nation-wide survey of what can and should be done to combat the problem of arthritis, arousing the public and the medical profession to the need for action in this field, and the financing of a program designed to accomplish those ends.

### NOTICES

#### NORFOLK DISTRICT MEDICAL SOCIETY

The scientific meeting of the Norfolk District Medical Society will be held at 8 p.m. on Tuesday, September 28, at the Boston Medical Library, 8 Fenway, Boston, entitled "Specialty Night."

#### PROGRAM

The Relief of Common Eye Disorders Seen in General Practice Dr. Edwin B. Dunphy  
The Relief of Common Ear, Nose and Throat Disorders Seen in General Practice Dr. Leighton F. Johnson  
Dermatology in Relation to General Practice Dr. Chester N. Frazier

#### SOUTH BOSTON MEDICAL SOCIETY

The next meeting of the South Boston Medical Society will be held on Monday, October 4, at 9 p.m., in the auditorium of the Carney Hospital. The speaker will be Dr. Frank H. Lahey.

#### SUFFOLK DISTRICT MEDICAL SOCIETY

The fall dinner of Suffolk District Medical Society will be given at the Harvard Club of Boston on Saturday, October 9, at 7 p.m. The Honorable Christian A. Herter, United States Congress, will speak on "The Effect of Foreign Policy on Domestic Questions."

Members of the Massachusetts Medical Society, wives and friends are cordially invited.

#### UROLOGY AWARD

The American Urological Association offers an annual award of \$1000 (first prize of \$500, second prize \$300 and third prize \$200) for essays on the result of some clinical or laboratory research in urology. Competition is limited to urologists who have been in such specific practice for not more than five years and to residents in urology in recognized hospitals. All interested should write to the secretary, Dr. Thomas D. Moore, 899 Madison Avenue, Memphis, Tennessee. Essays must be in his hands before February 15, 1949. The first-prize essay will appear on the program of the forthcoming meeting of the American Urological Association to be held at the Biltmore Hotel, Los Angeles, May 16 to 19.

# BACKGROUND

The use of cow's milk, water and carbohydrate mixtures represents the one system of

infant feeding that consistently, for over three decades, has received universal pediatric

recognition. No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri-Maltose.

## FACTORS FAVORING SUCCESSFUL TRANSMETATARSAL AMPUTATION IN DIABETES\*

HOWARD F. ROOT, M.D.†

BOSTON

ALTHOUGH the emergency character of infectious or early gangrenous lesions of the toes and feet of diabetic patients has long been recognized by most physicians, a new aspect of this problem is presented by the demonstration that in many diabetic patients a useful and serviceable foot can be preserved through the proper use of the transmetatarsal amputation.<sup>1,2</sup> Actually, in the last two years major amputations above the ankle have become less frequent at the New England Deaconess Hospital (Table 1). The danger inherent in minor lesions and the importance of teaching all older diabetic patients simple prophylactic measures appeared time and time again in the records of these 920 patients, many of whom cut a corn or drew blood by trimming a callus and walked on the foot for weeks before going to a physician for attention. Mildness of the diabetes is no protection against gangrene and, if overemphasized by the physician, gives the patient a false sense of security. Gangrene characteristically occurs in the obese, neglected diabetic patient with low insulin requirements and little or no glycosuria but with a malignant tendency to arteriosclerosis in the legs, the coronary vessels and the retinas. The injunction not to walk on a sore toe must be endlessly repeated: the insensitive foot is most dangerous and least resistant to infection.

The introduction of chemotherapy, especially penicillin, made possible control of infection to such a degree as to improve the possibility of carrying out with success conservative surgical procedures in diabetic patients. The group of patients so far operated upon have been selected with such attention to details that success has been obtained in 6 out of 7 operations. The analysis of the various factors making for success or failure in this group includes estimation of the blood supply, determination of the infection present and assessment of such factors as the duration and type of the diabetes and presence or absence of cardiac and renal complications.

It became evident early in this series that the line

separating failure and success was extremely narrow. In some patients successful healing occurred when the chances seemed remote. It was particularly true that certain patients who failed to heal promptly in the hospital did after a prolonged period at home, succeed in obtaining a thorough healing and useful foot. This paper summarizes

TABLE 1 *Types of Diabetic Amputation in 920 Cases at the New England Deaconess Hospital*

some of the clinical data in an attempt to present criteria for the selection of patients for operation.

### CLINICAL MATERIAL

One hundred and thirty-three transmetatarsal amputations were carried out on 122 different diabetic patients in the New England Deaconess Hospital between 1944 and September, 1947, by Drs. Leland S. McKittrick, John B. McKittrick, Norman L. Wilson, Theodore C. Pratt and Clifford C. Franseen. In 22 cases failure to heal is recorded, but in 3 of these, thigh amputation was not necessary. In 1 case after a period of many months at home healing finally occurred, and in 2 cases the result was termed a failure because of recurrence of ulcerations in anesthetic feet. The remaining 19 cases that failed to heal necessitated a subsequent thigh amputation.

The failures occurred chiefly in women, numbering 17 as against 5 failures in men. This preponderance is in excess of the proportion of women in the series since there were 74 female as against 59 male patients, in the total of 133 operations. This proportion is consistent with the sex incidence of

\*From the George F. Baker Clinic, New England Deaconess Hospital. Aided by a grant from the Eaton Laboratories Fund.

†Associate in Medicine, Harvard Medical School; physician-in-chief, New England Deaconess Hospital.

diabetes in middle and later life, although the sex incidence is equal in childhood diabetes

The duration of the diabetes must be considered at the same time as the age of patients at the time of operation. Thus, the duration was greatest in the 2 men operated upon in the fourth decade, both of whom had adequate blood supply to the foot but suffered typical neurogenic anesthetic feet. The

bulk of the operations were done in patients being between fifty-one and eighty years of age, totaling 52 out of 59 in men and 69 out of 74 in women. The duration of diabetes in these patients varied from nine years in the men between fifty-one and sixty years of age and fifteen years in the women between seventy-one and eighty years of age. The average duration of diabetes was ten years in the successful operations and fourteen years in the failures. It is evident that long duration of diabetes does not contraindicate this operation, although in general the longer the duration of diabetes in the patients in the older groups, the more serious the risk. The average age in the successful operations was sixty-

trauma was slight, consisting merely of the pricking of a blister that had broken or the cutting of a corn, and the commonest lesion was the infected callus with extension into the bone or joint. The lesions were described as localized or invasive according to the presence of lymphangitis or evidence of acute extending infection at the time of admission. It should be said that in this diabetic group practically all the lesions were invasive in the sense that the extension of infection from an infected corn or callus to a bone or joint with osteomyelitis, which is common in the diabetic patient, is rare in the person without the disease. To this extent it is a peculiarly invasive lesion. However, unless the lesion was accompanied by active extending invasive infection at the time of admission, it was considered to be localized. The invasive lesions numbered 62, and the localized lesions 71. In many cases in which lymphangitis or infection extended above the ankle the use of penicillin resulted in the subsidence of infection in the favorable cases to a degree that permitted the transmetatarsal amputation. The relation of invasive infection to successful operation is shown by the fact that successful operations were done in 50 cases of invasive infection. In the failures invasive infection was present in 12 out of 22 cases. In the cases of localized infection success was obtained in 61, and failure occurred in 10. It is evident therefore that success was not dependent upon the presence or the lack of the active invasive type of infection.

#### NATURE OF DIABETES

This group of patients stands out as composed of mild cases of diabetes of long duration in patients who had formerly been extremely obese. Table 3

TABLE 3 *Obesity and Weight Loss*

MAXIMUM WEIGHT	NUMBER OF CASES	AVERAGE MAXIMUM WEIGHT	AVERAGE WEIGHT AT OPERATION	AVERAGE WEIGHT LOSS	AVERAGE PERIOD OF WEIGHT LOSS	DURATION OF DIABETES AT OPERATION

Under 150	4	138	117	19	16	10 5
No data	5	—	—	—	—	—

one years, and in the failures it was sixty-five years (Table 2).

#### NATURE OF LESIONS

In this group, gangrene of one or more toes was present in 78 cases. In these 78 cases the pathological report also mentioned osteomyelitis. In another 19 cases osteomyelitis alone was recorded. In 36 cases the lesions were described as chronic ulcerations in the feet, with defective circulation or with neurotrophic disturbance of sensation. In all cases some type of trauma had been present. Often the

shows groups of the patients classified according to maximum weight. In 22 operations the maximum weight of the patient had been between 225 and 315 pounds, with an average of 245 pounds. The average maximum weight had been 208 pounds in 52 cases and 170 pounds in 50 cases. In only 4 cases had the maximum weight been less than 150 pounds. The loss of weight up to the time of the operation averaged in these different groups from 75 down to 19 pounds. The average period between the maximum weight and the time of operation showed very little variation in the different groups.

It is evident that serious foot lesions in mild diabetic patients depend in part upon an antecedent obesity and in part upon metabolic changes associated with great losses of weight due in large measure to relatively uncontrolled diabetes. The preceding treatment of diabetes in the group had as a whole been haphazard. Thus, in the successful cases, 99 patients had had no measured diet, and 21 patients among the failures had similarly had no measured diet. Actually only 13 patients in the series had been on a measured diet, and in those the period of a measured diet had been only a small part of the diabetic history. In the successful amputations insulin had been administered on the average for six years and seven months in 82 cases, and in 14 cases in this group insulin had been used for less than six months. In 15 of the successful operations no insulin had ever been used. Among the failures 20 patients out of the 22 had been taking insulin for an average of eight years and nine months. In this group two cases had taken no insulin. The striking factor here is the comparatively long period during which diabetes had existed without treatment by means of insulin. More important, however, is the fact that even though insulin had been used, the balance of diet and insulin had not been successfully or accurately maintained, with the result that glycosuria and hyperglycemia not only were present at admission but also had probably been present long before the recurrence and development of the lesion that brought about admission to the hospital.

#### CIRCULATION

The condition of the circulation, both general and local, is undoubtedly in many cases a chief factor in determining success. In the successful patients the blood pressure on admission averaged 167 systolic, 84 diastolic, whereas in the failures the value was 166 systolic, 84 diastolic. During the period of convalescence the average minimal blood pressure in the successful cases was 120 systolic, 76 diastolic, whereas in the failures the average minimal pressure was 133 systolic, 77 diastolic. Although in both groups patients showed slightly high blood pressures, the series as a whole was characterized by moderate hypertension of the systolic type, which naturally fell during rest more in the successful group than in the failures.

One might therefore suppose that a slightly greater degree of systemic hypertension was present in the failures. However, the local circulatory conditions undoubtedly were more important than the systemic blood-pressure readings. In the estimation of local circulation, presence or absence of normal palpable pulsations in the dorsalis pedis, popliteal and posterior tibial arteries was considered of chief importance. However, the appearance of the foot regarding atrophy of muscles on the affected side, the normally rapid or slow filling of the veins

after emptying, the development of rubor upon hanging the foot down, the presence of thin, shiny skin with loss of subcutaneous weight and the temperature of the foot and leg measured by palpation were taken into account. In the successful patients pulsation in the dorsalis pedis artery was absent in 76 and present in 35 cases whereas in the failures pulsation in the dorsalis pedis was absent in 21 cases. Almost the same situation was true of the pulsation in the posterior tibial artery. Pulsation of the popliteal artery is notoriously difficult to record with accuracy. A slight change in position of the patient makes the pulse easily felt one day and absent to palpation on another. However, among the successful cases the pulse was present in 91 and absent or not felt in 20 cases. It was absent in 6 of the 22 failures. If one single evidence of the character of peripheral circulation were to be relied upon the presence or absence of pulses in the dorsalis pedis vessel would probably be of greatest service provided that palpation were carried out with care and deliberation on more than one occasion and provided due allowance was made for the difficulty of feeling pulsation in a foot swollen with edema and inflammation.

In summary one may say that a deficient blood supply as indicated by absent pulsation in the dorsalis pedis, posterior tibial and popliteal arteries was a conspicuous feature in the cases in which failure occurred, and yet exception occurred in which healing proceeded successfully in spite of apparently hopelessly deficient circulation, so that some other factor must be assumed (Table 4). This factor may be humoral or in the tissue. It may be nutritional, or it may be concerned with the mechanism by which infection is controlled.

#### INFECTION

Cultures were made from the open lesions in 92 cases. *Staphylococcus aureus* was the most important single organism, but the combination of *Staph aureus* and a streptococcus occurred in 21 cases among the successful amputations and in 4 cases among the failures.

Hemolytic streptococcus alone was obtained in 7 cases. The hemolytic *Staph aureus* was obtained in 20 cases, and the *Staph aureus* in 21 cases. Other organisms such as diphtheroids, enterococcus, *Streptococcus faecalis* and *Clostridium welchii* (1 case) were reported in 16 cases. Seven of the 22 failures showed *Staph aureus*, 1 hemolytic *Staph aureus*, 3 hemolytic streptococcus and 4 a mixture of staphylococcus and streptococcus.

Unfortunately, no division of the *Staph aureus* was carried out, but it is evident that this species, in combination with other organisms, is at present the most frequent organism found in cultures obtained from open wounds. As yet no definite information is available whether the organisms are derived from outside sources or have been

carried to the lesion from within the patient's own body. The presumption is that they gain entrance into the tissue through injury and break in the skin, and that, once the skin is broken, the poor local resistance of the diabetic tissue enables the organisms to invade muscle, soft tissue and finally bone and joint spaces. The nature of the defect that makes diabetic patients so vulnerable to invasive infection by these organisms is a matter of speculation. For many years repeated studies have failed to disclose in the blood or body fluids a mechanism directly related to the staphylococcus. In animals made diabetic the study of staphylococcal lesions is not easy because many animals do not develop staphylococcal infections in a manner comparable with that of human beings. It seems more likely

particularly when there has been a great loss of weight and tissue cachexia. Recently, the relation of vitamins and the disturbances of nutrition associated with avitaminosis has been intensively studied, and particularly in experimental diabetes attention has been given to the effect of thiamine chloride deficiency. As yet, however, no clear picture of the mechanism by which diabetic tissues lose the power of resisting invasion by the staphylococcus and streptococcus has been presented.

#### *Anesthetic Feet*

Other factors in this group of patients may be emphasized. In 24 of the successful cases various degrees of anesthesia of the toes, foot or even of the lower leg were present, whereas in 2 of the failures

TABLE 4 *Factors Affecting 133 Transmetatarsal Amputations among 122 Diabetic Patients*

that the resistance to such organisms is a matter of tissue resistance rather than a humoral mechanism. Patients with diabetes of long duration are well known to show a variety of tissue changes,

this factor was prominent. Deficient sensation in diabetic feet has been a matter of clinical observation for many years. It is associated with the loss of reflexes and sometimes with changes in the cen-

Failure	22	12	10	9	15	7	1	4

which are measurable both by pathological techniques and by clinical methods. It is also well known that normal glycogen may be greatly reduced in content in diabetic acidosis as well as in states of diabetic malnutrition. Although the level of glucose may increase in normal tissue and in the skin of diabetic patients not under good control, at the same time the glycogen content of the diabetic skin is greatly reduced. The concentration of glycogen is directly affected and increased when adequate insulin and dietary treatment is carried out. Similar changes in the lipid content of diabetic tissues—notably, liver, kidneys and nerve tissues—have been recorded. An increase in the lipid content of the blood except the cholesterol content occurs under conditions of diabetic maladjustment, par-

tral nervous system indicated by an increase of protein in the cerebrospinal fluid. The importance of the finding of anesthesia lies in the fact that these feet healed readily after surgery and will remain healed so long as the patient is in bed or spending only a short period on his feet. Continued use of the feet in walking results sooner or later in pressure areas, ulcerations and infection, and the resistance to infection of this group of patients seems even lower than that in the group as a whole. Frequently associated with this anesthesia, which usually is not accompanied by any serious impairment of blood supply, there may be an increase in the protein of the cerebrospinal fluid and a well marked increase in capillary fragility. In this group the spinal-fluid protein was above 50 mg per 100

cc in 24 of the successful cases and 5 of the failures. It was below 50 mg in 18 successful cases and 4 failures. Albuminuria, hypertension and retinitis were common. In 36 of the successful cases and 12 of the failures hemorrhages and exudates were present in the evegrounds. Serious impairment of vision was common. However, in 37 cases hemorrhages and exudates were not noted although it must be said that in many of these cases the examinations were not carried out by an ophthalmologist.

PREVIOUS LESIONS

In 51 patients of this series there had been previous infections of the streptococcus and staphylococcus type, including ulcerations, carbuncles and boils. In 56 cases amputations of a toe or in a

This group is often described as made up of patients with mild diabetes. If one takes as evidence of mildness the amount of insulin required and glycosuria present, this statement may be true. Actually, in this group the average maximum insulin dosage was 31 units for successful cases and 48 units for the failures, and at discharge, after a prolonged period of hospital treatment, the average was 17 units for the successful cases and 24 units for the failures. One may say, therefore, that the failures represented a somewhat severer type of diabetes, however, even this conclusion is not safe since the difference in the insulin dosage is slight and readily accounted for on the basis of more serious infection in the cases of failure. The important point, however, is to recognize the fact that

TABLE 4 (Continued)

few cases of a leg had previously been performed. This group, therefore, consisted of patients in whom by and large the arteriosclerotic process had been in evidence for a considerable period, and the ampu-

the severity of diabetes in this group of patients is not to be measured by the glycosuria or the requirement of insulin dosage. Actually, a better measure is some assessment of the effect of diabetes

tation through the transmetatarsal area was in many cases done as a matter of desperation to save one foot when the other had already been amputated. The frequency of these infections suggests again the well known fact that, although in the course of healing one assumes that local immunity has developed and antibodies occur, not only is there no persisting immunity but also these patients seem to represent a group in which a specific vulnerability to the organisms continues. As a practical consequence the teaching given to diabetic patients should emphasize all precautions, not merely directed against trauma but particularly designed to prevent and control infections whenever any break of the skin has permitted the entry of the organisms.

in producing loss of weight, malnutrition, vascular disease, impairment of nerve supply and finally and most important of all, the destruction of the normal resistance against invasive infection by the staphylococcus and the streptococcus.

FOLLOW-UP STUDY

A follow-up summary to April, 1948, of all patients undergoing transmetatarsal amputations at the New England Deaconess Hospital is presented in Table 5. The striking improvement in the selection of patients is shown by the fact that in 1944 and 1945, 45 out of 56 operations were successful, 10 failed to heal and required thigh amputations and 1 patient died of coronary occlusion. In the second period, 1946-1947 only 14 failures

occurred in 95 operations, and in 1948 only 1 unsuccessful operation was performed in 19. A single postoperative death occurred in the total of 170 operations.

Examination of the patients or a doctor's report in 1948 revealed that of the 45 patients who left the hospital in 1944 and 1945 with a healed transmetatarsal amputation 30 are still healed and walking, 4 walk with some limitation, 5 of the patients

foot is a useful foot and stands the strain of walking for a long time.

SUMMARY

An analysis of 133 transmetatarsal amputations in 122 cases of diabetes at the New England Deaconess Hospital is presented. The danger of infections or early gangrene resulting from cutting of corns or trimming of callus among diabetic

TABLE 5 Results of Follow-up Study in 170 Transmetatarsal Amputations

†1948

who required thigh amputation in 1944 and 1945 are walking with a prosthetic appliance, and the other 5 are included among the 12 patients who died of coronary occlusion and other vascular complications after discharge from the hospital. In the period 1946-1947 out of 81 successful operations 70 patients are still healed and walking, 5 more have limited walking, 14 who suffered a thigh amputation are still walking with a prosthetic appliance and 3 are dead. One of the most striking facts is that in only 2 cases out of 144 patients who left the hospital with a healed transmetatarsal amputation has a subsequent thigh amputation become necessary on the same side. In these cases trauma to the leg led to gangrene at the level of the ankle in 1 and at the level of the shin in the other. The deficiency of the blood supply was so great that thigh amputation followed. However, if the patient once succeeds in healing a transmetatarsal amputation the

patients is stressed. All persons with diabetes should be constantly warned against walking on a sore toe.

Failure to heal occurred in 22 of the amputations, and 19 patients required subsequent thigh amputation (failures occurred chiefly among female patients). In all cases trauma, usually slight, was followed by gangrene. Most of the patients had mild diabetes and had once been overweight. The blood pressures among the failures were higher than those among the successful cases.

Results have steadily improved since 1944, owing to selection of patients and the introduction of chemotherapy and penicillin.

## BRONCHIAL ADENOMA\*

CARLTON R. SOLDER, M.D.,† AND J. W. KINGSLEY, JR. M.D.‡

BOSTON

**B**RONCHIAL adenoma was first recognized sixty-five years ago, and yet it received little mention in the literature until relatively recently. Since the publication of Reisner's<sup>1</sup> article in 1928 several excellent clinical and pathological descriptions of this tumor have been written. The increasing awareness of bronchial adenoma has led to its more frequent recognition and to a more thorough understanding of the altered respiratory physiology and of the pulmonary complications to which it predisposes. The recent advances in thoracic surgery have broadened the therapeutic approach to these tumors, as well as to other types of pulmonary lesions. The purpose of this communication is to review the literature and to present our experience with bronchial adenoma.

The incidence of bronchial adenoma has been stated to be approximately 6 per cent of all primary bronchial tumors.<sup>2</sup> It comprised 12 per cent of 278 neoplasms diagnosed bronchoscopically by Clerf and Bucher.<sup>3</sup> Of 217 histologically proved primary lung tumors encountered at the Lahey Clinic since 1930, 15 were bronchial adenomas, an incidence of 6.9 per cent. Adams<sup>4</sup> has discussed some of these cases in a previous report. It is of interest to note that the diagnosis has been confirmed in 9 cases during the past three years, whereas only 6 cases of bronchial adenoma were discovered over the preceding fifteen years. For ease of description the cases have been numbered in the order in which they were diagnosed, and the pertinent features of each are summarized in Table I.

The origin of bronchial adenoma remains unsettled. It appears that most adenomas arise in the submucosa of the bronchial wall, probably from the bronchial glands or ducts. From this point of origin growth progresses into the bronchial lumen as well as extrabronchially. Brunn and Goldman<sup>5</sup> stated that extrabronchial extension occurs in 90 per cent of cases, however, this was definitely found in only 7 of the cases.

Because of the uncertain origin and variable morphology of these tumors, numerous terms have been suggested for bronchial adenoma. Nevertheless, it is believed that the use of this designation is desirable until the situation is clarified.

With few exceptions bronchial adenomas are situated in a primary bronchus, where they can be readily visualized through the bronchoscope. In the 15 cases reported herein, the tumor was seen by the bronchoscopist in 12. In Case 8 the growth

was in a segmental bronchus of the left upper lobe, where it could not be demonstrated. In Case 13 there was definite narrowing of the right-lower-lobe bronchus from external pressure without evidence of intrabronchial growth. At operation the latter was found to arise in the dorsal division of the right-lower-lobe bronchus and to possess an extra-bronchial portion several times larger than that within the lumen. In Case 5 bronchoscopy was not performed.

When seen bronchoscopically an adenoma appears as a rounded, pink or reddish-purple mass, the surface of which is often bosselated. The tumors are usually attached by a broad base but rarely have a distinct pedicle that permits the entire mass to move with respiration or instrumentation (Case 3). Not infrequently blood vessels can be seen on the surface of the tumor. As a rule, there is no visible ulceration. Adenomas are notorious for profuse bleeding following manipulation, and death has been reported from aspiration of blood after biopsy.<sup>6</sup> Instrumentation did not cause serious bleeding in any of our cases.

If an adenoma is satisfactorily visualized, its distinctive appearance usually differentiates it from carcinoma. Whereas carcinoma often produces fixation of the bronchus, this almost never occurs in the presence of adenoma. Carcinomas are frequently ulcerated, and although they may bleed freely at biopsy this is seldom troublesome. Microscopical examination of biopsy material is essential in the differential diagnosis but is not without its shortcomings. In the first place, the forceps may not penetrate the tumor deeply enough to obtain characteristic cells, and secondly, squamous metaplasia of the surface epithelium or distortion of the cells may lead to an erroneous diagnosis of carcinoma. Serial sections minimize the possibility of error.

Histologically bronchial adenomas have been divided into two main types: carcinoid and mixed tumor, or cylindroma. The latter is considered by some investigators to possess greater malignant potentialities than the more common carcinoid type.<sup>7,8</sup> Womak and Graham<sup>9</sup> prefer the term "mixed tumor" for all adenomas because of their resemblance to mixed tumors of the salivary glands and the occasional presence of bone and cartilage. The cellular structure of the carcinoid type is comparable to that of appendiceal carcinoids, parathyroid adenomas and basal-cell carcinoma.<sup>10</sup>

Differences of opinion regarding the potential malignancy of bronchial adenoma have interfered with the adoption of uniform therapy. Foster-

1	F	33	4 yr	Cough sputum hemoptysis recurrent fever sweats and pleurisy	Diminished breath sounds rales over right lower lobe	Atelectasis right lower lobe no filling of dorsal division right lower lobe bronchus on bronchography	Tumor mass right lower lobe bronchus
2	F	34	1 yr	Cough hemoptysis and chest discomfort	Negative	Soft tissue mass lower pole of right hilus	Tumor mass right lower-lobe bronchus
3	F	23	2½ yr	Cough wheeze chest discomfort, chills fever and weight loss	Diminished breath sounds right lower and middle lobes increased breath sounds right upper lobe	Obstructive emphysema right lung	Right main bronchus almost completely occluded by pedunculated tumor which could be moved 1 cm. but bleeding
4	M	30	6 yr	Cough sputum pressure in chest and hemoptysis	Diminished breath sounds over right lower lobe	Soft-tissue mass right hilus	Tumor mass in right lower-lobe bronchus active bleeding on biopsy
5	F	38	5 yr	Cough sputum pneumonia three times	Negative	Infiltration and bronchiectasis right lower lobe bronchogram done	No bronchoscopy done
6	M	39	6 yr	Cough sputum hemoptysis repeated pneumonia	Diminished resonance and breath sounds left lower lobe	Atelectasis and bronchiectasis left lower lobe	Tumor mass obstructing left-lower-lobe bronchus
7	M	41	2 yr	Vague abdominal distress and hemoptysis	Negative	Questionable mass right hilus	Tumor mass at junction of right middle and lower-lobe bronchi
8	F	29	2½ yr	Cough dyspnea and chest discomfort	Inspiratory lag on left	Tumor and segmental atelectasis bronchiectasis left upper lobe	No tumor seen
9	F	51	8 mo	Repeated hemoptyses	Negative	Mass right hilus partial atelectasis right lower lobe	Tumor mass within right lower-lobe bronchus extending into middle-lobe bronchus
10	M	42	3 yr	Cough and repeated hemoptyses	Negative	Negative	Pedunculated tumor right main bronchus encroaching upon carina
11	M	13	1 yr	Cough wheeze dyspnea chest discomfort repeated pneumonia and weight loss	Diminished breath sounds and resonance left lower lobe	Atelectasis left lower lobe	Tumor left main bronchus
12	M	37	16 mo	Cough hemoptysis and chest discomfort	Negative	Infiltration midportion of left lung field	Tumor left upper lobe bronchus extending to lower-lobe bronchus
13	F	49	4 yr	Cough sputum, pleurisy and severe hemoptysis	Diminished breath sounds and resonance right lower lobe	Tumor mass right hilus atelectasis right lower lobe	Narrowing of right lower lobe bronchus from external pressure no tumor visible within bronchus
14	F	47	18 mo	Cough purulent sputum hemoptysis repeated pneumonia and weight loss	Diminished breath sounds and resonance left lower lobe	Atelectasis left lower lobe	Tumor obstructing left-lower lobe bronchus and extending into upper lobe bronchus
15	M	32	8 mo	Cough sputum wheeze dyspnea severe hemoptysis once	Wheeze over left lower lobe when patient was lying on left side rhonchi	Negative	Tumor mass arising in left main bronchus extending into upper lobe bronchus and almost completely filling lower lobe bronchus

of malignancy in 2 cases. Adams, Steiner and Bloch<sup>14</sup> reported 5 cases, 2 with distant metastases, which they considered to be malignant. Metastasis years after the original diagnosis of cylindroma. Lymph-node involvement was present in 5 of 10 cases reported by Chamberlain and Gordon.<sup>17</sup>

Graham and Womack<sup>18</sup> believe that some adenomas become malignant with loss of their original identity. Local infiltration by tumor cells has been

with tumor cells present in two hilar lymph nodes<sup>19</sup>

From these facts one must conclude that bronchial adenoma is a potentially malignant neoplasm

TABLE 1 (Continued)

CASE No	TREATMENT	PATHOLOGY	RESULTS OF FOLLOW UP STUDY	COMMENT
1	Local removal and electrocoagulation twice removal of right lower and middle lobes	Carcinoid type with invasion and infiltration of wall large extrabronchial portion bronchiectasis	Patient well 6½ yr after lobectomy	Despite repeated examinations and removal of recurrent growth pressure from extrabronchial portion led to bronchostenosis and bronchiectasis
2	X-ray therapy local removal and electrocoagulation	Infiltrating carcinoid type	Patient well after 6½ yr	—
3	Local removal electrocoagulation of base.	Infiltrating carcinoid type	Patient well after 4½ yr	—
4	Removal of right middle and lower lobe	Low grade adenocarcinoma arising from adenoma, with involvement of 2 hilar lymph nodes	Patient well after 4 yr	Seropositive congenital syphilis present
5	Removal of right lower lobe	Infiltrating carcinoid type at orifice of right lower lobe bronchus with large extrabronchial extension bronchiectasis	Patient well after 2½ yr	Diagnosis not made preoperatively
6	Removal of left lower lobe	Infiltrating carcinoid type bronchiectasis	Patient well after 2 yr	—
7	Removal of right middle and lower lobes	Infiltrating carcinoid type with ossification of stroma	Patient well after 2 yr	—
8	Removal of left upper lobe	Tumor in segmental bronchus left upper lobe carcinoid type bronchiectasis	Patient well after 20 mo	—
9	Removal of right middle and lower lobes	Infiltrating carcinoid type	Patient well after 14 mo	—
10	Local removal and electrocoagulation twice	Infiltrating carcinoid type	Patient well after 7 mo	—
11	Partial removal pneumonectomy (left) elsewhere.	Infiltrating carcinoid type	No follow-up study	—
12	Recurrence 2 months after local removal and electrocoagulation pneumonectomy (left)	Infiltrating carcinoid type, with ossification of stroma	Dysphagia after 5 mo	Pressure on esophagus by bronchial stump
13	Removal of right, middle and lower lobes	Tumor dorsal division of right lower lobe bronchus infiltrating carcinoid type with large extrabronchial extension	Patient well after 6 mo	Immediate operation because of severe hemoptysis
14	Removal of left lung	Infiltrating carcinoid type bronchiectasis left lower lobe.	Patient well after 5 mo	—
15	Removal of left lung	Infiltrating carcinoid type	—	Patient operated on too recently for follow up observations

a frequent finding and was detected in 14 cases. In Case 4 the pathological diagnosis was "low-grade adenocarcinoma arising from bronchial adenoma

The grade of malignancy is apparently low, inasmuch as there are no cases on record in which death has resulted from sudden rapid growth of the tumor

Carter,<sup>11</sup> Jackson et al.<sup>12</sup> and Clerf and Bucher<sup>3</sup> concluded that the tumors are essentially benign. On the other hand, Wessler and Rabin<sup>13</sup> found evidence

to the liver has been described by Anderson<sup>14</sup> and by Holley.<sup>16</sup> Laff and Neuburger<sup>7</sup> found malignant change with spread to the opposite lung thirteen

9	F	51	8 mo	Repeated hemoptyses	Negative	Mass right hilus partial atelectasis right lower lobe	Tumor mass within right lower-lobe bronchus extending into middle-lobe bronchus
10	M	42	3 yr	Cough and repeated hemoptyses	Negative	Negative	Pedunculated tumor right main bronchus encroaching on carina
11	M	13	1 yr	Cough wheeze dyspnea chest discomfort repeated pneumonia and weight loss	Diminished breath sounds and resonance left lower lobe	Atelectasis left lower lobe	Tumor left main bronchus
12	M	37	16 mo	Cough hemoptysis and chest discomfort	Negative	Infiltration midportion of left lung field	Tumor left upper lobe bronchus extending to lower-lobe bronchus
13	F	49	4 yr	Cough sputum pleurisy and severe hemoptysis	Diminished breath sounds and resonance right lower lobe	Tumor mass right hilus atelectasis right lower lobe	Narrowing of right lower lobe bronchus from external pressure no tumor visible within bronchus
14	F	47	18 mo	Cough purulent sputum hemoptysis repeated pneumonia and weight loss	Diminished breath sounds and resonance left lower lobe	Atelectasis left lower lobe	Tumor obstructing left lower lobe bronchus and extending into upper lobe bronchus
15	M	32	8 mo	Cough sputum wheeze dyspnea severe hemoptysis once	Wheeze over left lower lobe when patient was lying on left side rhonchi	Negative	Tumor mass arising in left main bronchus extending into upper-lobe bronchus and almost completely filling lower lobe bronchus

of malignancy in 2 cases. Adams, Steiner and Bloch<sup>14</sup> reported 5 cases, 2 with distant metastases, which they considered to be malignant. Metastasis

years after the original diagnosis of cylindroma. Lymph-node involvement was present in 5 of 10 cases reported by Chamberlain and Gordon.<sup>17</sup>

of atelectasis. There may be a noticeable disparity in the size and expansion of the two hemithoraces. Compensatory emphysema of the uninvolved lobes is not uncommon in cases with complete occlusion of the bronchus. The fact that in 6 patients physical examination of the chest was negative serves to emphasize the fact that abnormal physical signs are not essential to a diagnosis of bronchial adenoma.

ROENTGENOLOGIC FINDINGS

Roentgenograms of the chest reveal abnormalities in the majority of cases of adenoma of the bronchus, however special technics are frequently necessary to establish a reasonably exact diagnosis. Most observers have mentioned atelectasis as the most common finding followed by inflammatory

infiltrations of these findings in 4 cases (Fig 3 and 4). Obstructive emphysema was present in 1 patient

FIGURE 1 Plain Film in Case 4 Showing a Rounded Soft-Tissue Mass at the Lower Pole of the Right Hilum

FIGURE 2 Inflammatory Infiltration of the Majority of the Left-Lower Field in Case 12

(Fig 5). Chest roentgenograms were normal in 2 cases. Overexposed (grid or Bucky) films are valu-

FIGURE 3 Tumor Mass Superior atelectasis and Bronchectasis of the Left Upper Lobe in Case 8. The adenoma was resected and a bronchogram

able in detecting intraluminal tumors which as a rule are less readily discernible than extrabronchial

infiltration, a visible tumor mass and obstructive emphysema. It must be emphasized that none of these findings are diagnostic of bronchial adenoma. Whether present singly or in combination they indicate nothing more than mechanical interference with normal bronchial function. The visible tumor mass produced by an adenoma cannot be differentiated from other types of bronchial tumors by roentgenologic study alone. Final diagnosis must rest upon the bronchoscopic and histopathological appearance.

Atelectasis alone was demonstrated in 3 cases; a tumor mass (Fig 1) in 3; inflammatory infiltration (Fig 2) or bronchiectasis in 2; and various combinations of these findings in 4 cases (Fig 3 and 4). Obstructive emphysema was present in 1 patient.

with widespread metastases — a common finding in the usual type of bronchiogenic carcinoma

### CLINICAL CONSIDERATIONS

#### *Age and Sex*

Adenoma of the bronchus is largely a disease of the younger age groups. Sixty per cent of the 15 patients were under 40 years of age, the converse of the age distribution of bronchiogenic carcinoma

TABLE 2 *Age and Sex Distribution*

AGE	NO OF PATIENTS	FEMALE PATIENTS	MALE PATIENTS
11-20	1	0	1
21-30	3	2	1
31-40	3	3	2
41-50	4	2	2
51-59	2	1	1
Average age		38.0	36.3

The age range was from 13 to 59 years, with an average of 37.15 years (Table 2). Eight patients (53 per cent) were women.

#### *Duration of Symptoms*

It is not uncommon to discover bronchial adenoma as the cause of respiratory symptoms of several years' standing. The duration of symptoms among these patients varied from 8 months to 6 years, with an average of 2.7 years. This parallels the experience of others.

#### *Symptoms*

**Cough and sputum.** Cough, the commonest symptom of bronchial adenoma, was the initial symptom in 7 and was present in 13 patients. At the outset the cough is likely to be mild, but with growth of the tumor the bronchial irritation increases and the cough becomes more distressing. This symptom may be most troublesome at night or when the patient assumes a particular position. The presence of sputum depends largely upon the degree of bronchial obstruction produced by the adenoma. Early, therefore, sputum may be absent or mucoid in character owing to the increased bronchial secretion. When bronchial obstruction and infection supervene, with or without actual bronchiectasis or abscess, the sputum tends to become purulent. Sputum was present to some degree in 8 of the patients in this series.

**Hemoptysis.** Hemoptysis is one of the outstanding manifestations of adenoma of the bronchus. It occurred one or more times in 11 of the 15 patients, in 3 it was the initial symptom. In Case 13 hemoptysis was of such severity and persistence as to necessitate prompt surgical intervention. Typically, the bleeding is sudden in onset, brisk and fairly abrupt in cessation. In the female patients hemoptysis was not related to the menses. It seems likely

that in most cases bleeding results from the rupture of a blood vessel on the surface of the adenoma since, as mentioned above, the tumors are almost never found to be ulcerated. The presence of bronchiectasis constitutes another possible source of hemorrhage.

**Wheeze.** Wheeze was an outstanding complaint of 3 patients, 2 of whom were referred to the clinic with a presumptive diagnosis of bronchial asthma. One extremely important feature of the wheeze accompanying bronchial adenoma is its tendency to be localized to a definite area. In addition, it may be transient and vary with change of position, this is especially true of the pedunculated adenoma as exemplified by Case 3. Wheeze tends to disappear as the bronchus becomes completely obstructed.

**Dyspnea.** Although as a rule not extreme, dyspnea may be distinctly troublesome. This complaint was present in 4 cases. Moderate diminution of vital capacity may result from atelectasis or obstructive emphysema. If the latter is of sufficient degree to produce mediastinal shift, the function of the sound lung will be compromised. Dyspnea is often more pronounced with partial than with complete bronchial obstruction.

**Chest discomfort.** Varying degrees of chest discomfort occur fairly frequently in association with bronchial adenoma. In general, this is mild and is often described as a feeling of fullness or pressure in the chest. The most severe type of pain encountered is due to pleuritis. Six patients complained of mild chest pain.

**Pulmonary infection.** Patients with bronchial adenoma are prone to develop pulmonary sepsis. Often there is a history of recurrent bouts of pneumonia involving the same lobe, or of slowly resolving pneumonia. Bronchial obstruction may, in addition to producing pneumonitis, lead to bronchiectasis or abscess formation. In other cases the clues to the underlying process are less obvious, the clinical manifestations being limited to fever, either intermittent or continuous, sweats and, not infrequently, weight loss. Four patients had recurrent episodes of pneumonia. Two others had repeated chills and fever. Pleurisy was present in 2 cases. Three patients lost from 12 to 25 pounds in weight.

### PHYSICAL FINDINGS

Abnormal findings on physical examination are in direct proportion to the degree of bronchial obstruction and the extent of pulmonary involvement distal to the tumor. In the presence of partial obstruction of a bronchus decreased resonance and distant breath sounds, with or without wheeze, may be detected over the involved lobe. Rales or rhonchi will be added in the presence of pneumonitis or bronchiectasis. Obstructive emphysema develops distal to adenomas that permit ingress of air but occlude the bronchus during expiration. With complete bronchial obstruction the findings are those

carina. It may be employed to promote bronchial drainage prior to surgical resection, thereby reducing the degree of infection.

Surgical resection holds the advantage of removing not only the entire tumor but also the infected portion of the lung. Bronchiectasis in itself is an indication for resection, regardless of whether or not the tumor can be completely removed bronchoscopically. In addition, surgical resection precludes the possibility of malignant degeneration, which, although relatively infrequent, cannot be entirely discounted. It might be argued that resection is too radical for sessile adenomas without demonstrable extrabronchial tumor or infection, and yet the probability of later complications after local removal is sufficiently great to make lobectomy or pneumonectomy the preferred method of treatment.

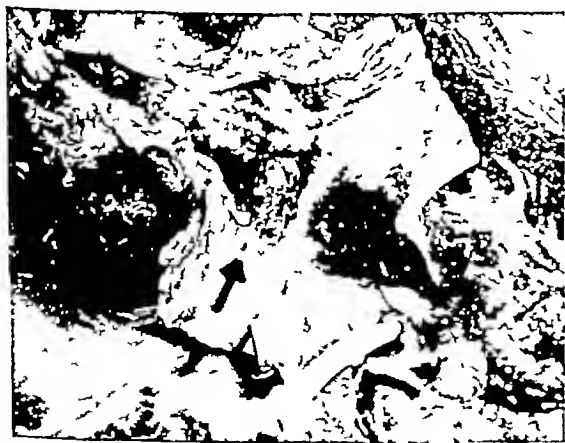

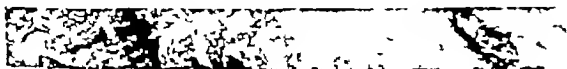

FIGURE 6 Surgical Specimen in Case 15 Showing a Small Adenoma in situ at the Bifurcation of the Left Main Bronchus. The tumor mass arose in the main bronchus, extended into the upper-lobe bronchus and almost completely occluded the lower-lobe bronchus. A portion of the adenoma had previously been removed for biopsy.

This is especially true today with the great reduction in mortality and morbidity that has resulted from improved surgical technic and from the use of antibiotics.

In 3 patients of the present series the adenomas were removed bronchoscopically without a recurrence to date. Case 2 was treated by local removal prior to the evolution of the present policies of treatment, there has been no recurrence after six and a half years. The adenoma in Case 3 had a distinct pedicle, which rendered bronchoscopic removal practicable, this patient has remained well for four and a half years. In Case 10 the tumor arose in the

right main bronchus and encroached upon the carina, electrocoagulation was carried out without recurrence after seven months. Another patient (Case 1) was bronchoscoped seven times over a six-year period, although the endobronchial portion of the tumor was successfully obliterated, extra-bronchial growth produced progressive broncho-

FIGURE 7 Bronchial Adenoma in Case 15, Showing Intra-luminal Growth and Infiltration of the Bronchial Wall, with Replacement of the Normal Glandular Structure ( $\times 11\frac{1}{2}$ ).

stenosis, bronchiectasis developed, and lobectomy became necessary. In Case 12 the tumor involved both the left-upper-lobe and the left-lower-lobe bronchi, therefore, it was decided that trial by local removal was justified in an attempt to avert pneumonectomy. The growth recurred within two months, and pneumonectomy was performed without further delay. In Case 15 the tumor was located at the bifurcation of the left-upper-lobe and left-lower-lobe bronchi (Fig 6), pneumonectomy was done without trial of local removal. Infiltration of the bronchial wall by tumor cells is shown in Figure 7.

The left lung was removed in 3 cases. Two lobes were resected in 5 patients, and a single lobe in 3. The remaining patient underwent pneumonectomy elsewhere and has been lost to follow-up observation. There were no operative deaths. Five months after removal of the left lung the patient in Case 12 developed difficulty in swallowing, barium studies revealed distortion of the esophagus by the bronchial stump, without obstruction. The other 10 patients have been completely relieved of their symptoms and have remained well for from six months to six and a half years postoperatively, except 1 (Case 15), who was operated on too recently to be included in the follow-up report.

#### SUMMARY AND CONCLUSIONS

Bronchial adenoma constituted 6.9 per cent of all pathologically proved primary bronchial tumors.

masses. Fluoroscopy and roentgenograms taken during forced expiration aid in discovering obstructive emphysema and should therefore be utilized whenever partial bronchial obstruction is suspected. Body-section roentgenography, as advocated by Lowry and Rigler,<sup>2</sup> has not been employed in this clinic.

Bronchography occasionally proves of value and was employed in 2 cases. The chief indications for

biopsy material usually establish the diagnosis. The main points of differentiation from bronchiogenic carcinoma have been discussed. Bacteriologic studies of bronchial secretions are important in ruling out tuberculosis, however, the two conditions can coexist. An intrabronchial foreign body can be distinguished in most cases by the history of aspiration.

#### TREATMENT

Therapy of bronchial adenoma has been almost entirely confined to local removal and to surgical resection. Irradiation has been given a limited trial but has proved of questionable value. This form of treatment was employed in Case 2 with temporary decrease in cough and hemoptysis, but without

FIGURE 4 Tumor Mass at the Right Hilum in Case 9, Producing Partial Atelectasis of the Right Lower Lobe

lipiodol studies are to determine the site of a suspected tumor when bronchoscopy fails to do this, and to ascertain the presence of bronchiectasis. When the latter is being sought, it may be necessary to remove a portion of the adenoma prior to bronchography to obtain satisfactory filling. In Case 1 bronchograms showed obstruction of the dorsal division of the right-lower-lobe bronchus. In Case 5 bronchiectasis was demonstrated, but the tumor mass, which was largely extrabronchial, was not apparent.

#### DIAGNOSIS

Bronchial adenoma should be considered as a diagnostic possibility in every young patient who presents a history of chronic cough, hemoptysis and repeated pulmonary infections. Likewise, the possibility of adenoma should be entertained in the presence of atelectasis, localized wheeze, obstructive emphysema or unilateral bronchiectasis. The prime requisite to the diagnosis is to suspect bronchial adenoma and to obtain bronchoscopy. Visualization of the tumor and microscopic study of

FIGURE 5 Obstructive Emphysema of the Right Lung in Case 3, Produced by the Valve-like Action of a Pedunculated Bronchial Adenoma

Note the low position of the right leaf of the diaphragm and shift of the heart to the left

visible change in the tumor itself, which was later removed by electrocoagulation.

Bronchoscopic removal affords good results in selected cases, specifically those in which the adenoma has a distinct pedicle and no extrabronchial extension, and in which irreversible pulmonary damage has not occurred. Local removal is the only possible approach to adenomas that involve the

It is believed that these experiences may be of value to others who wish to develop similar facilities

In May, 1946, a tentative plan for the treatment of selected psychiatric patients in the House of Mercy Hospital, Pittsfield, Massachusetts, was embarked on. The plan was formulated with the co-operation of the hospital medical director, Dr Reo J Marcotte, who recognized the responsibility the hospital would assume, but also recognized the service that could be performed for the benefit of the community. The House of Mercy Hospital is a general hospital of 200-bed capacity. It is the largest of three in the City of Pittsfield, which has a population of about 55,000. There is also an additional population of 75,000 in the county. The neuropsychiatric program was started without any significant expense to the hospital. In the Outpatient Department, several rooms that had not previously been fully utilized were designated as the "treatment area." The nurses assigned to the Outpatient Department plan their schedule so that they are available for treatments, which are given at approximately the same time each morning. A male attendant is also available at such treatment periods. Personnel of this type are especially necessary when electric convulsive therapy is administered. In the treatment area, subcoma insulin and sodium amytal interviews are also carried out. Subcoma insulin treatments are supervised by the same nurses. Patients are treated on an inpatient or outpatient basis. Inpatients who have improved are often discharged, and treatment is continued on an outpatient basis.

This psychiatric program is carried on without assistance from hospital interns or residents. Although it would be desirable to have such doctors participate in the program there has been a marked shortage of house officers in the smaller general hospitals. Medical supervision of the program depends entirely on myself, the only physician taking part in the program. I spend all my mornings in the hospital, and in this way all treatments can be properly supervised.

The success of the plan for the management of psychiatric patients depends largely on selection. Since there are no locked facilities, a significant number of patients must be rejected. It is apparent that disturbed, overactive, unco-operative and some paranoid patients cannot be accepted for treatment. In the psychotic group of patients, depressions comprise the largest number. Psychotic patients are accepted for treatment when it appears that they can be helped by electric shock therapy. Psychoneurotic patients are accepted when psychotherapy in a hospital setting is considered advantageous, and when it is believed that somatic treatment will be of value. The largest number of these patients have severe anxiety tension states and have been difficult to manage on the basis of office treatment. Such patients are treated with psycho-

therapy and subcoma insulin. Patients with conversion states are hospitalized and are treated with psychotherapy, aided by sodium amytal interviews.

Table 1 presents a report of the patients treated during the year 1947. It is realized that the numbers are not impressive. However, the figures should be considered in relation to the size of the community. No attempt is made to evaluate the somatic treatments used, since these have been adequately discussed elsewhere.

It can be seen that a higher percentage of psychotic patients were treated as outpatients. This was often due to the patient's inability to co-operate

TABLE 1 *Inpatients and Outpatients Treated during 1947*

in a general hospital. It would probably have been better to institutionalize several of these patients. However, neither the patient nor the family was able to make such a decision. To refuse treatment to such patients would have meant that they would merely remain at home.

The management of psychiatric patients in a general hospital, without locked facilities, has significant advantages. Patients are treated without legal commitment or certification. At an early date the family and patient can more readily accept the psychiatric diagnosis and the indicated treatment. Relatives are reassured when they realize that the patient is to be treated in the same hospital where he would receive care for pneumonia or appendicitis. This minimizes any question of social stigma. In this community it means that the patient does not have to be removed to some other city, since there are no other psychiatric hospital facilities in Pittsfield. Patients who are treated on an outpatient basis spend only short periods away from their home setting.

These advantages not only are important in their social implications but also include significant economic elements. Since the patient remains in the community, time and money are not spent in traveling to visit him. Hospitalization insurance has recently been liberalized and gives definite benefits to the psychiatric patient. In this community a large industrial organization has liberalized its hospitalization policy and allows both inpatient and outpatient treatment of psychiatric patients. Blue Shield in Massachusetts makes extra allowances to the physician for the

encountered at the Lahey Clinic over a period of eighteen years. Adenomas can usually be visualized bronchoscopically, and their characteristic appearance in most cases serves to differentiate them from carcinoma. Bronchial adenoma is a potentially malignant tumor, but the malignancy is of a low grade.

Sixty per cent of bronchial adenomas occurred in patients less than forty years of age. The incidence was slightly greater in female patients. A history of chronic cough, hemoptysis and repeated pulmonary infections, or findings of atelectasis, localized wheeze, obstructive emphysema or unilateral bronchiectasis are indications for bronchoscopy on a suspicion of adenoma.

Inasmuch as surgical resection removes the infected lung tissue as well as the entire tumor and prevents malignant degeneration, it is the treatment of choice in the majority of cases. Local removal may suffice for pedunculated adenomas without extrabronchial extension and without irreparable parenchymal destruction, however, the possibility of recurrence necessitates repeated bronchoscopic examinations.

## PSYCHIATRY IN A GENERAL HOSPITAL OF A SMALL CITY\*

SAMUEL M. TARNOWER, M.D.†

PITTSFIELD, MASSACHUSETTS

PSYCHIATRY is slowly becoming part of general hospital organization. This branch of medicine was preceded by neurology, which is concerned with more obvious physical disease and usually does not involve overt abnormalities of behavior. The patient with a psychiatric diagnosis is not welcome in a general hospital. His diagnosis meets the resistance of outmoded attitudes. His illness is still not devoid of some social stigma. Hospital personnel are too apt to associate memories of excitements and unco-operative behavior with psychiatric disorders. To circumvent such conditions, psychiatric patients are admitted daily to general hospitals with nonpsychiatric diagnoses. Bennett<sup>1</sup> reports that in 1940 there were 4302 general hospitals in the United States, more than 90 per cent of which did not permit the admission of a patient with a known psychiatric diagnosis.

In spite of such resistant attitude toward psychiatric patients, some definite progress has been made. Many hospitals offer psychiatric consultation. However, only hospitals with locked pavilions offer any active or complete treatment. Such locked pavilions are few in number and are usually limited

to large hospitals or those associated with teaching institutions. Heldt's<sup>2,3</sup> reports on the psychiatric division of the Henry Ford Hospital were notable and early exceptions. It is of interest that at the Henry Ford Hospital, psychotic patients were admitted even though locked facilities were not available. However, a full-time psychiatric staff cared for these patients.

With the advent of shock therapies, new opportunities for treatment of psychiatric disorders have been offered to the average general hospital. Selected patients, even though suffering from major disorders, can fit into the hospital setting for a reasonable period. Fetterman<sup>4</sup> has emphasized the value and feasibility of treating psychiatric patients in a general hospital. During a recent visit to the Royal Victoria Hospital in Montreal, I was able to view an entire building, the Alan Memorial, devoted to the treatment of neurosis and psychosis without the aid of locked wards. In the Army, small hospitals often had to care for psychotic patients. In civilian medicine the smaller general hospitals have made practically no attempt to care for the psychiatric patient. My experiences in developing a practical degree of psychiatric service in a general hospital of a small city are reported below.

\*From the House of Mercy Hospital.  
†Neurologist and psychiatrist, House of Mercy Hospital, instructor in neurology and psychiatry, Albany Medical College.

The peritoneal cavity was explored through a transverse incision and a tense cystic mass (Fig 1) exposed. This proved to be a thin-walled, unilocular cyst measuring more than 12 by 10 by 5 cm and under tension. Its attachment was immediately proximal to the fimbriated end of the left fallopian tube. There was a little gas and meconium in the large bowel, the small bowel being collapsed and compressed by the mass of the cyst. The cyst was removed intact, and its color changed from a light blue, before removal, to a pinkish yellow after removal. The intestinal tract from stomach to rectosigmoid was examined and considered normal. The wound was closed.

Review of the anesthesia chart revealed an immediate improvement in pulse, color and amplitude of respiration after delivery and removal of the cyst.

The patient's weight at birth was 6 pounds, 6 ounces. Immediately after operation it was 6 pounds, including the dressing. Convalescence was delayed by low serum protein with edema, which was corrected and she was discharged

resembles the fimbriated end of a fallopian tube. There is also noted a nipple of tissue surrounded by a silk suture. On section there is revealed an estimated 150 cc. of clear yellow fluid with the odor of formalin. The inner lining is smooth and glistening with prominent blood-vessel markings, and there are several small cystic nodules opposite the cylindrical structure on the external surface described above. They measure 0.2 to 0.5 cm in diameter and contain a clear yellow fluid. The wall is of uniform thickness throughout.

Microscopical examination revealed two sections stained by hemotoxylin and eosin and two Giemsa-stained sections,

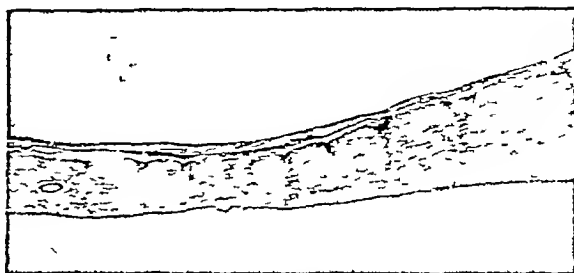

FIGURE 2

which include the fallopian tube and a segment of the cyst wall. The mucosa of the fallopian tube is drawn into its usual folds. The muscularis is moderately cellular and somewhat edematous. The cyst wall is largely composed of fine strands of connective tissue, which are loosely interwoven. The lining of the cyst is composed of from three to eight layers of flattened cells with elongated nuclei resembling fibroblasts, with a moderate number of cells with round tense nuclei resembling granulosa cells. Nowhere in the section is there an evidence of inflammation or neoplasm (Fig 2).

The diagnosis was follicular cyst of ovary and fallopian tube.

The estrogenic assays made in the Fearing Research Laboratory gave the following result: the cyst fluid was found to contain 50 international units of estrogenic activity per cubic centimeter. No ketonic estrogen was demonstrable, 80 per cent of the total activity went into the estradiol fraction. This division of estrogenic material is similar to that found in follicular cysts of the ovary in older persons, which however, contain more estrogenic activity (25 to 450 international units per cubic centimeter).

### SUMMARY

The case of a thirty-four-hour-old infant from whom a gigantic follicular cyst of the ovary was successfully removed is presented.

A report of the histologic examination and assay of contents of the cyst is made.

A review of the literature reveals only 1 case of successful operation in a newborn infant for a similar lesion.

FIGURE 1

34 days after operation, weighing 7 pounds 4 ounces. In October, 1947, she was considered to be in good condition and developing normally.

The specimen was immediately photographed. It was then covered with gauze, soaked in physiologic saline solution and placed in a container with ice. The specimen was taken to the Fearing Research Laboratory, Free Hospital for Women, Brookline, Massachusetts, where Drs. O. Watkins Smith and George V. Smith were consulted about a possible assay of the cyst fluid. The intact cyst weighed 340 gm. It was aspirated, and approximately 300 cc. of fluid removed for assay. The removed fluid was partially replaced by a solution of formalin, and the needle puncture area was ligated. The specimen was examined in the Department of Pathology, Children's Hospital, Boston. The microscopical slides were reviewed by Drs. George V. Smith and Arthur T. Hertig, who concurred in the microscopical diagnosis made by the Children's Hospital Laboratory.

The pathological report was as follows:

The specimen consists of a roughly spherical fluctuant translucent, formalin-fixed mass weighing 340.7 gm and measuring 12 by 10 by 5 cm. The external surface is smooth and glistening and is mottled purple red in color. Through the wall are seen numerous fine vascular markings. Along one edge there is a tubular structure measuring 2.5 by 3.0 cm. One edge is closed by a silk suture, and the other re-

administration of shock therapy. In all, these changes have brought the economics of a psychiatric disorder close to that of other medical and surgical diseases.

It is recognized that this plan has definite disadvantages. Suicidal attempts are always a potential danger. Fortunately, there have been no such accidents in the hospital. However, there have been three unsuccessful suicidal attempts in patients receiving electric shock therapy on an out-patient basis. It can be seen that the plan often places an unusual responsibility on the family. Inpatients do not have the advantage of a planned occupational-therapy program.

### SUMMARY AND CONCLUSIONS

The general hospital of the smaller cities can offer treatment for psychiatric patients.

A description is given of the development of the program for treatment of psychoneurosis and psy-

choses in the House of Mercy Hospital, Pittsfield, Massachusetts.

A program for psychiatric treatment can be carried out under the supervision of one psychiatrist.

The success of the program is largely dependent on the selection of patients.

Treatment of the psychiatric patient in a general hospital has significant medical, social and economic advantages.

## CLINICAL NOTE

### GIANT OVARIAN CYST IN A NEWBORN INFANT\*

LIEUTENANT WILLIAM I. NEIKIRK (MC), U.S.N.R.,†  
AND  
HENRY W. HUDSON, JR., M.D.‡

OVARIAN cysts producing symptoms in early life are rare, and in the newborn infant almost unknown. Symptoms are almost invariably the result of torsion. Diagnosis is seldom made prior to operation. Doran,<sup>1</sup> in 1888, described the post-mortem appearance of a seven-month premature infant who survived birth by a few minutes as follows:

The abdomen was distended, the subcutaneous veins were prominent. The integuments above the level of the umbilicus were discolored through ecchymosis.

In 1936 Haines and Edgerly<sup>2</sup> made a review and reported cases of cysts being removed for abdominal symptoms but not for symptoms suggesting intestinal obstruction. A similar review was presented by Benjamin<sup>3</sup> in 1941.

In 1942 Bulfamonte<sup>4</sup> described a case quite similar to that reported below.

### CASE REPORT

A female infant was born, at term, on April 22, 1947, at 8:15 a.m. The mother had been greatly impressed by the large amount of amniotic fluid when the membranes ruptured spontaneously 2 hours before birth. She estimated the amount as several times greater than that with any of her previous seven pregnancies. No abnormality of the infant was noted by the two physicians present at delivery, nor by a physician who saw the baby at 10 a.m. because of cyanosis relieved by aspiration of mucus. The infant went to breast 12 hours after delivery and every 4 hours thereafter, and the mother noted that little or nothing was taken and that the infant was continuously spitting "saliva," which at the end of the first 24 hours of life was yellow stained.

On April 23 at 8 a.m. physical examination revealed the abdomen to be markedly distended, and several engorged veins were noted over the upper part. The percussion note was tympanic over the upper abdomen and dull in the flanks and over the lower abdomen. Peristaltic sounds were audible only in the right upper quadrant and faintly in the right flank. No mass was made out, but a sense of increased resistance was observed in the left lower quadrant. No fluid wave was demonstrated. The examiner was unable to introduce his little finger into the anus. No meconium had been passed.

Examination of the blood was not significant except that the white-cell count was 19,100. X-ray examination was reported as showing moderate distention of the stomach and numerous loops of small bowel and parts of the large bowel. These gas-filled loops lay primarily in the right upper quadrant and the right posterior gutter. The left anterior portion of the abdomen was occupied by a fairly homogeneous shadow without any evidence of identifying characteristics. The descending colon and sigmoid contained a small amount of gas. An attempt to outline the large bowel by injection of lipiodol showed only the distal 10 cm. The oil could not be introduced beyond this point, presumably because of a considerable amount of meconium rather than an organic lesion. The general impression was one of almost complete intestinal obstruction, probably resulting from an intrinsic lesion or anomaly of development. Distention increased rapidly, and by 4:30 p.m. was extreme. Cyanosis was noted. The superficial veins of the abdominal wall were greatly dilated. About 1 cm. below the xiphoid a line of demarcation was apparent, below which the skin was dusky, the legs were definitely cyanotic. Venous obstruction and intestinal obstruction seemed evident. A catheter was passed into the stomach, but little or no air obtained. Operation was performed 34 hours after birth. Various diagnoses, all concerned with possible causes of intestinal obstruction, were entertained.

§The possible association of hydramnios and anomalies of the intestinal tract in the fetus is recognized by various authorities.

The peritoneal cavity was explored through a transverse incision and a tense cystic mass (Fig 1) exposed. This proved to be a thin-walled, unilocular cyst measuring more than 12 by 10 by 5 cm and under tension. Its attachment was immediately proximal to the fimbriated end of the left fallopian tube. There was a little gas and meconium in the large bowel, the small bowel being collapsed and compressed by the mass of the cyst. The cyst was removed intact, and its color changed from a light blue, before removal, to a pinkish yellow after removal. The intestinal tract from stomach to rectosigmoid was examined and considered normal. The wound was closed.

Review of the anesthesia chart revealed an immediate improvement in pulse, color and amplitude of respiration after delivery and removal of the cyst.

The patient's weight at birth was 6 pounds, 6 ounces. Immediately after operation it was 6 pounds, including the dressing. Convalescence was delayed by low serum protein with edema, which was corrected, and she was discharged

## MEDICAL PROGRESS

## METHEMOGLOBINEMIA AND SULFHEMOGLOBINEMIA\*

CLEMENT A. FINCH, M.D.†

BOSTON

THE appearance of severe cyanosis may alarm the patient and presents a diagnostic problem to the attending physician. Recognition of the cause of the cyanosis and the specific blood pigment involved permits the separation of conditions connoting serious underlying disease from those of benign origin. An increased amount of reduced hemoglobin in cardiac or pulmonary disease is frequently responsible for mild cyanosis. The more intense degrees of cyanosis seen clinically are due to abnormal pigments within the red cell—methemoglobin and sulfhemoglobin. The relative capacity of each of these pigments to produce cyanosis is shown by the fact that about 5 gm. of reduced hemoglobin per 100 cc. of blood is required to produce recognizable cyanosis,<sup>1</sup> whereas 1.5 gm. of methemoglobin and less than 0.5 gm. of sulfhemoglobin have comparable effects. Rarely, cyanosis is produced by intravascular hemolysis with the formation of methemoglobin and methemalbumin<sup>2</sup> in the plasma. In such cases, the associated anemia, hemoglobinuria and side effects of the toxic agent are conspicuous, and the cyanosis is relatively mild. The presence of hemoglobin and its derivatives in the plasma differentiates this group from intracellular cyanosis, although combined reactions may occur. This discussion is limited to abnormal pigments within the red cell that produce cyanosis.

## INTRACELLULAR METHEMOGLOBIN

Hemoglobin iron is normally ferrous, and in its role as an oxygen carrier is oxygenated and de-oxygenated without change in valence. In methemoglobin the iron has been oxidized from the ferrous to the ferric form.<sup>3</sup> The change is an easily reversible one and in itself is not accompanied by any red-cell damage or destruction.<sup>4-7</sup> Methemoglobin is unable to transport oxygen and should therefore be regarded as a pigment that is temporarily inert.

## Identification

When methemoglobinemia is suspected, blood should first be drawn into a tube containing heparin or oxalate and centrifuged. If the plasma is clear, hemolysis and abnormal serum pigments are excluded as a cause of cyanosis. The whole blood may then be shaken in air for fifteen minutes. Nor-

mally, the blood becomes bright red as all pigment is converted to oxyhemoglobin. If it remains dark, abnormal intracellular pigments are present. The blood should then be diluted ten to one hundred times with water and examined with a hand spectroscope. The dark band of methemoglobin is seen at 630 millimicrons (Fig. 1). The band disappears immediately after two or three drops of 5 per cent potassium cyanide are added, differentiating it from the sulfhemoglobin band at 618, which remains fixed.<sup>8,9</sup> The same bands may be seen through the earlobe of the patient. Methemoglobin may be determined quantitatively by gasometric means<sup>10</sup> or colorimetrically.<sup>11</sup> Horecker<sup>12,13</sup> has described its absorption spectrum in the infrared and devised a method for its measurement in this range. In all quantitative determinations in the visible range, the importance of controlling the pH is shown by the spectrophotometric studies of Austin and Drabkin.<sup>14</sup> Blood should be examined within one or two hours of withdrawal since in most cases intracellular methemoglobin on standing spontaneously reverts to the ferrous form.<sup>15</sup>

*Hemoglobin-Methemoglobin Equilibrium of the Erythrocyte*

The relation between hemoglobin and methemoglobin is more clearly understood by a comparison of its equilibrium in three systems—that is, in water, in plasma and within the erythrocyte (Fig. 2). Under aerobic conditions an aqueous hemoglobin solution is progressively converted to methemoglobin. In plasma, free hemoglobin is only partially converted to methemoglobin.<sup>16,17</sup> By means of certain reducing substances the plasma appears to be able to maintain the equilibrium at somewhat over 50 per cent ferrous hemoglobin. In contrast, the normal erythrocyte contains at most only 1 or 2 per cent of methemoglobin.<sup>10,18-20</sup> The question then arises regarding how hemoglobin within the erythrocyte is maintained in the ferrous form.

Although devoid of a nucleus, the red cell energetically reduces methemoglobin by an enzymatic process in which glucose and lactate are the principal substrates.<sup>21-28</sup> The presence of methemoglobin activates this process since the resting oxygen consumption and glucose utilization of the red cell are only slight, whereas in the presence of methemoglobin there is an appreciable

\*From the Medical Clinic, Peter Bent Brigham Hospital, and the Department of Medicine, Harvard Medical School.

†Associate in medicine, Harvard Medical School; associate in medicine, Peter Bent Brigham Hospital.

increase. Methemoglobin offers an available source of oxygen for carbohydrate breakdown and in the process is itself reduced. It appears that hexose monophosphate, reduced pyridine nucleotide and perhaps Kiese's "methemoglobin reductase" are involved in this reduction. Since with lysis of the red cell the phosphorylating mechanism breaks down and pyridine nucleotide is destroyed, the system can operate only in the intact cell. Clinical states of methemoglobinemia can be caused either by dysfunction of this reconversion mechanism, with-

librium between oxidized and reduced hemoglobin within the erythrocyte it would be anticipated that much larger amounts of oxidants would be needed to produce successive increments of methemoglobin. Indeed in animals it is almost impossible

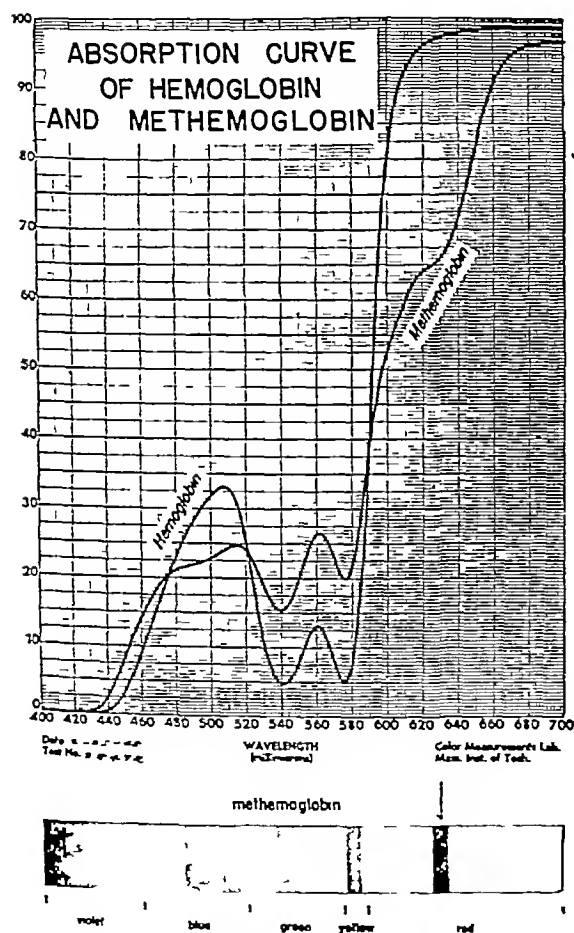

FIGURE 1 Spectrophotometric Absorption of Methemoglobin. In the upper portion the percentage transmission of a solution of oxymethemoglobin is compared with a solution of both methemoglobin and oxymethemoglobin. The decreased transmission (or increased light absorption) of the methemoglobin solution at 500 and 630 millimicrons is evident. Below is a spectrum as visualized through a hand spectroscop (adjusted to the wavelength-scale above) in which the typical band of methemoglobin in the red is shown by an arrow.

out which circulating hemoglobin would be at the mercy of the plasma oxidation-reduction potential, or by the action of oxidants which produce methemoglobin more rapidly than the cell mechanism is able to reduce it (Fig 2). With the existing equi-

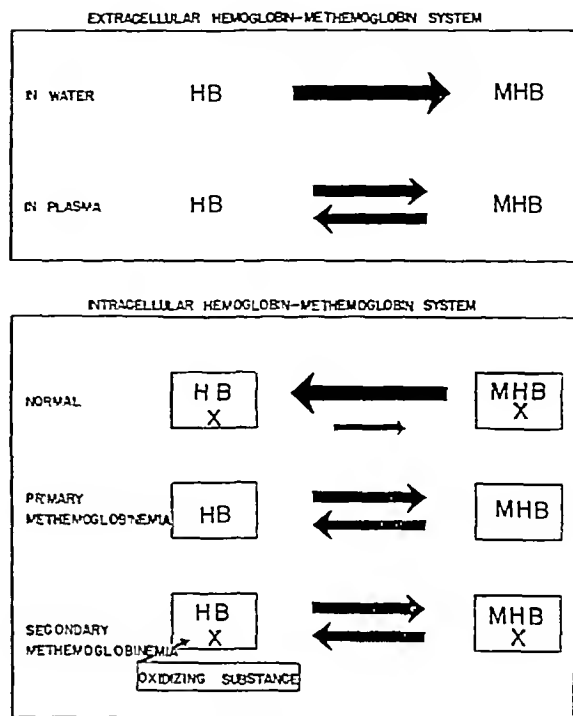

FIGURE 2 Hemoglobin (HB) and Methemoglobin (MHB) Equilibria

X represents the normal-functioning methemoglobin reconversion system of the erythrocyte. The arrows designate the nature of the equilibria under different conditions. Blood hemolyzed in water is progressively and completely converted to methemoglobin. It is apparent that in respect to the hemoglobin-methemoglobin equilibrium the red cell in congenital methemoglobinemia is similar to hemoglobin suspended in plasma. In both methemoglobin is found in amounts slightly below 50 per cent. Although the red-cell mechanism (X) maintains a ratio of about 99 HB/MHB, oxidizing substances may temporarily displace this equilibrium.

to displace this equilibrium to the lethal point with certain aniline derivatives<sup>29-31</sup>

### Physiologic Effects of Methemoglobinemia

Symptoms from methemoglobinemia are attributable to the anoxia produced by the lowered oxygen capacity of the blood or to side effects of the agent producing methemoglobinemia. At concentrations of 20 per cent methemoglobin, working subjects complained of mild fatigue and showed abnormally high blood lactic acid levels.<sup>32</sup> In dogs with methemoglobin concentrations over 40 per cent, a compensatory increase in cardiac output has been observed.<sup>33</sup> A shift in the oxygen dissociation curve to the left has been shown to occur in

drug-induced methemoglobinemia, seriously handicapping the unloading of oxygen in the tissues<sup>24, 25</sup> Despite this, levels of 30 to 50 per cent methemoglobin may occur without producing severe symptoms.<sup>5</sup> The lethal concentration of methemoglobin in dogs is about 85 to 90 per cent.<sup>36</sup> The exact level at which coma and death supervene in man is not known.

### Treatment of Methemoglobinemia

Methemoglobin in the body may be reconverted to hemoglobin by reducing substances, by the nor-

role in red-cell metabolism was the observation of Harrop and Barron<sup>40</sup> that red-cell respiration and carbohydrate utilization are increased greatly by methylene blue. In tissue respiration methylene blue is able to substitute for the cytochrome enzymes. Mammalian red cells lack these enzymes. Since the dye accelerates red-cell respiration and methemoglobin reduction to a state comparable to that found in nucleated avian erythrocytes, it may be postulated that it acts as a more efficient oxidation-reduction transport system than that present in the mammalian erythrocyte. Methylene blue reverts methemoglobin at a rate far greater than that of the normal cell mechanism, as shown in Figure 3.<sup>39, 41-43</sup>

The misleading statement is sometimes made that methylene blue may either reduce methemoglobin or produce it depending on the dose employed. However, over a dosage range of a fraction of a milligram to 10 mg per kilogram of patient's body weight, methylene blue acts to revert methemoglobin to hemoglobin and *clinically significant amounts of methemoglobin are not produced*.<sup>44-46</sup> Doses of 500 mg administered intravenously during ten minutes in man have produced symptoms of nausea, precordial and abdominal pain, dizziness and headache, and mental confusion for as long as twelve hours.<sup>47</sup> Larger doses up to 7 gm administered slowly have been given without symptoms but have produced anemia in man.<sup>46</sup> Still larger doses in animals have produced hemolytic anemia, pulmonary edema and death.<sup>48, 49</sup> In the usual therapeutic dose of 1 or 2 mg per kilogram of body weight, given over a five-minute period, however, no such reactions have been reported.

Specific treatment for methemoglobinemia has been discussed elsewhere.<sup>39</sup> After the pigment has been identified, 1 mg of methylene blue per kilogram of body weight in adults and 2 mg in infants may be injected intravenously slowly over a period of five minutes.\* If cyanosis has not disappeared within an hour, a second dose of 2 mg per kilogram of body weight should be given. Methylene blue may also be given orally in doses of 3 to 5 mg per kilogram.

### CLINICAL METHEMOGLOBINEMIA

#### Primary Methemoglobinemia

In the literature at least 16 established cases of congenital methemoglobinemia have been reported,<sup>50-61</sup> in 8 of which there was a familial incidence. In 5 other cases information regarding the congenital aspect was incomplete.<sup>62-65</sup> Symptoms consisting of fatigue, exertional headaches and reduced exercise tolerance are surprisingly mild. I have seen 1 patient with a methemoglobin level of 40 per cent who was able to indulge in strenuous

\*For intravenous injection 1 per cent solutions are prepared by Parke Davis and Co. and by William H. Rover Incorporated. The usual adult dose is 7 cc.

### RATE OF METHEMOGLOBIN REVERSION

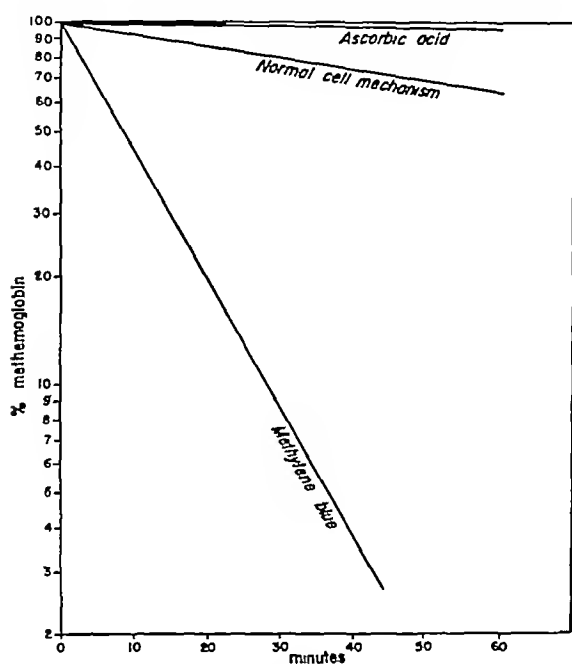

FIGURE 3 Various Reversion Rates Calculated from Data Presented Elsewhere.<sup>39</sup>

The ordinant represents the percentage of the initial level of methemoglobin, usually between 2 and 5 gm per 100 cc in the patients studied.

mal cell-reconversion mechanism or by catalysis of this normal mechanism.

Ascorbic acid<sup>27</sup> and glutathione<sup>28</sup> are effective as reducing agents, although the only one used clinically has been ascorbic acid. This substance reduces methemoglobin slowly in vivo and even in large doses does not approach the speed of the normal cell-reconversion system.<sup>39</sup> This material is of little value, therefore, in conditions in which the normal cell-reconversion mechanism may have been exceeded—that is, in secondary methemoglobinemia (Fig. 3).

Methylene blue brings about reversion of methemoglobin not by its own reduction capacity but through acceleration of the normal cell-reconversion mechanism. Perhaps the first suggestion of its

activity without symptoms. This remarkable tolerance to methemoglobinemia may be explained by its chronicity by the secondary polycythemia compensating for inert pigment and by the normal oxygen-dissociation curve in contrast to secondary methemoglobinemia.<sup>5</sup> Reports indicate that without treatment the majority of these patients tend to reach equilibrium at about 40 per cent methemoglobinemia.

In blood drawn from these patients, methemoglobin shows no tendency to revert to hemoglobin spontaneously. The biochemical lesion, a failure of the normal reconversion mechanism, represents a congenital defect of the erythrocyte. Methemoglobin accumulates slowly until a point of equilibrium is reached. In 1 patient studied it was produced at the rate of 3 per cent of the total pigment a day.<sup>5</sup> The ascorbic acid of the serum is decreased in these patients despite adequate diets,<sup>55-59-61</sup> and the plasma has little or no capacity to reduce methemoglobin.<sup>60</sup> This suggests that reducing substances are being expended in the reduction of methemoglobin to hemoglobin. These reducing substances may be regarded as a secondary line of defense of the body against pigment oxidation. Patients may be adequately treated with either ascorbic acid or methylene blue. Lian<sup>55</sup> first described the efficacy of ascorbic acid in congenital methemoglobinemia, and this has been verified by others.<sup>5, 56, 59-61</sup> In doses of 100 to 500 mg a day by mouth the methemoglobin levels are reduced to 8 to 10 per cent of the total pigment. This might be anticipated since the rate of reconversion by ascorbic acid is considerably greater than the spontaneous methemoglobin accumulation in these patients.<sup>39</sup> Methylene blue is likewise effective in a daily dosage of 100 to 300 mg by mouth.<sup>5</sup>

Secondary Methemoglobinemia

*That due to drugs.* Certain drugs or their degradation products have the capacity of converting hemoglobin to methemoglobin. These drugs preferentially oxidize hemoglobin, and reducing substances in the body such as glutathione and ascorbic acid offer no protection against this oxidation.<sup>66</sup> Some of these drugs are listed in Table I. It seems probable that the amino and nitro groups of these compounds are responsible for the methemoglobinemia. Nitrites, sulfonamides and aniline derivatives are perhaps the most important drugs in the production of methemoglobinemia.

Nitrites produce methemoglobin rapidly and quantitatively within limits when studied in vitro or in vivo, although the exact chemical interaction is not clear.<sup>78</sup> The many ways in which nitrites gain access to the blood stream have presented numerous clinical problems. Cyanosis may be produced by excessive use of amyl nitrite or nitroglycerin, or by inhalation of nitrous gases as reported in arc welders.<sup>79</sup> Ingested nitrates may be converted to

nitrites by intestinal bacteria, and, after absorption from the intestine produce methemoglobin. Cases have been reported in infants drinking well water that had high concentration of nitrates,<sup>80-82</sup> from the use of bismuth subnitrates in the treatment of diarrhea,<sup>83, 84</sup> from ammonium nitrate used as a diuretic<sup>85</sup> and from food high in nitrates.<sup>86</sup> Methemoglobin is especially prone to occur after nitrate ingestion in patients with ulcerative lesions of the bowel.

Sulfonamides — particularly sulfanilamide, but also prontosil, sulfathiazole and sulfapyridine — frequently produce both methemoglobin and sulfhemoglobin.<sup>87-94</sup> No report has been found of this

type of cyanosis due to sulfadiazine or sulfamerazine. Rimington and Hemmings<sup>95</sup> have attempted to correlate the porphyrinuric action of these drugs with their methemoglobin production capacity.

Aniline dyes are particularly dangerous because of their ability to penetrate the intact skin,<sup>96-99</sup> producing methemoglobinemia through the action of breakdown products — that is, phenylhydroxylamine and aminophenol. Contact with dyed blankets, laundry marks on diapers and freshly dyed shoes has produced methemoglobinemia. A single washing of the dyed article will prevent this. Recently several cases of methemoglobinemia have been observed in children swallowing colored crayons.<sup>100</sup> Owing to their extensive use phenacetin and acetanilid are two of the more common drugs producing methemoglobinemia.<sup>101</sup>

Associated red-cell damage varies considerably from one drug to another and even with the same drug from one patient to another. The over-all picture is best represented as a spectrum with methemoglobin formation at one end and extensive red-cell destruction at the other. Nitrites cause chiefly methemoglobinemia although Heinz bodies and anemia have been described in chronic poison-

drug-induced methemoglobinemia, seriously handicapping the unloading of oxygen in the tissues<sup>34, 35</sup> Despite this, levels of 30 to 50 per cent methemoglobin may occur without producing severe symptoms.<sup>5</sup> The lethal concentration of methemoglobin in dogs is about 85 to 90 per cent.<sup>36</sup> The exact level at which coma and death supervene in man is not known.

### Treatment of Methemoglobinemia

Methemoglobin in the body may be reconverted to hemoglobin by reducing substances, by the nor-

role in red-cell metabolism was the observation of Harrop and Barron<sup>40</sup> that red-cell respiration and carbohydrate utilization are increased greatly by methylene blue. In tissue respiration methylene blue is able to substitute for the cytochrome enzymes. Mammalian red cells lack these enzymes. Since the dye accelerates red-cell respiration and methemoglobin reduction to a state comparable to that found in nucleated avian erythrocytes, it may be postulated that it acts as a more efficient oxidation-reduction transport system than that present in the mammalian erythrocyte. Methylene blue reverts methemoglobin at a rate far greater than that of the normal cell mechanism, as shown in Figure 3.<sup>39, 41-43</sup>

The misleading statement is sometimes made that methylene blue may either reduce methemoglobin or produce it depending on the dose employed. However, over a dosage range of a fraction of a milligram to 10 mg per kilogram of patient's body weight, methylene blue acts to revert methemoglobin to hemoglobin and *clinically significant amounts of methemoglobin are not produced*<sup>44-46</sup> Doses of 500 mg administered intravenously during ten minutes in man have produced symptoms of nausea, precordial and abdominal pain, dizziness and headache, and mental confusion for as long as twelve hours.<sup>47</sup> Larger doses up to 7 gm administered slowly have been given without symptoms but have produced anemia in man.<sup>48</sup> Still larger doses in animals have produced hemolytic anemia, pulmonary edema and death.<sup>48, 49</sup> In the usual therapeutic dose of 1 or 2 mg per kilogram of body weight, given over a five-minute period, however, no such reactions have been reported.

Specific treatment for methemoglobinemia has been discussed elsewhere.<sup>39</sup> After the pigment has been identified, 1 mg of methylene blue per kilogram of body weight in adults and 2 mg in infants may be injected intravenously slowly over a period of five minutes.\* If cyanosis has not disappeared within an hour, a second dose of 2 mg per kilogram of body weight should be given. Methylene blue may also be given orally in doses of 3 to 5 mg per kilogram.

### CLINICAL METHEMOGLOBINEMIA

#### Primary Methemoglobinemia

In the literature at least 16 established cases of congenital methemoglobinemia have been reported,<sup>50-61</sup> in 8 of which there was a familial incidence. In 5 other cases information regarding the congenital aspect was incomplete.<sup>62-66</sup> Symptoms consisting of fatigue, exertional headaches and reduced exercise tolerance are surprisingly mild. I have seen 1 patient with a methemoglobin level of 40 per cent who was able to indulge in strenuous

### RATE OF METHEMOGLOBIN REVERSION

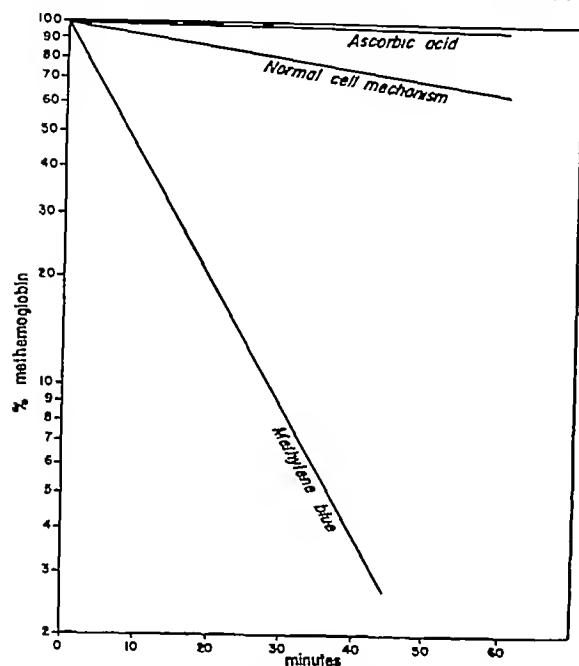

FIGURE 3 Various Reversion Rates Calculated from Data Presented Elsewhere<sup>39</sup>

The ordinant represents the percentage of the initial level of methemoglobin, usually between 2 and 5 gm per 100 cc in the patients studied.

mal cell-reconversion mechanism or by catalysis of this normal mechanism.

Ascorbic acid<sup>37</sup> and glutathione<sup>38</sup> are effective as reducing agents, although the only one used clinically has been ascorbic acid. This substance reduces methemoglobin slowly in vivo and even in large doses does not approach the speed of the normal cell-reconversion system.<sup>39</sup> This material is of little value, therefore, in conditions in which the normal cell-reconversion mechanism may have been exceeded—that is, in secondary methemoglobinemia (Fig. 3).

Methylene blue brings about reversion of methemoglobin not by its own reduction capacity but through acceleration of the normal cell-reconversion mechanism. Perhaps the first suggestion of its

\*For intravenous injection 1 per cent solutions are prepared by Parke Davis and Co. and by William H. Rorer, Incorporated. The usual adult dose is 7 cc.

excreted<sup>25</sup> Inhalation of amyl nitrite is even more rapid in its antidotal action

### SULFHEMOGLOBINEMIA

Sulfhemoglobin is an abnormal pigment, not found in the body under ordinary circumstances. It exists exclusively inside the red cell except in cases of sulfhemoglobinemia with associated hemolysis.<sup>115</sup> The exact nature of sulfhemoglobin is unknown, but available evidence indicates that there is a closed porphyrin ring with no increase in easily split iron.<sup>126</sup> It is to be distinguished from choleglobins.<sup>127</sup> The latter are open ring structures and a biproduct of sulfhemoglobin formation by hydrogen sulfide *in vitro*. They have not been demonstrated in man. It is possible that the transformation to sulfhemoglobin is the result of displacement of one of the N atoms in the pyrrole ring by sulfur.<sup>128</sup> Although it has not been prepared in pure form, its spectrum shows a strong band at 618 (Fig. 4), which has been the basis of spectroscopic and colorimetric methods of identification.<sup>8, 11, 129</sup> It can be qualitatively identified with a hand spectroscope since its band is unaffected by potassium cyanide, but is dispersed by hydrogen peroxide.<sup>2, 8, 9</sup>

The formation of sulfhemoglobin does not indicate cell damage, but does represent an irreversible change in hemoglobin pigment. In workers who became cyanotic from exposure to trinitrotoluene, the disappearance of sulfhemoglobin was identical to the disappearance rate of transfused normal erythrocytes as determined by Ashby counts.<sup>130</sup> The life span of the involved cells was not altered. Thus, whereas methemoglobin due to drugs rapidly reverts, sulfhemoglobinemia is a stable compound cleared from the blood over as long as three or four months. Although hemoglobin is rendered inert as an oxygen carrier, it seems unlikely that sufficient amounts of sulfhemoglobin are ever produced clinically to endanger the life of the patient.

### CLINICAL SULFHEMOGLOBINEMIA

#### That Due to Drugs

Drugs causing sulfhemoglobinemia include the group described above as methemoglobin producers (Table 1). There are frequent reports of its production by the earlier sulfonamide derivatives,<sup>91</sup> by phenacetin and acetanilid<sup>101</sup> and by aniline.<sup>97</sup> Oxidizing agents, such as phenylhydrazine, hydroxylamine and paraminophenol, catalyze the production of sulfhemoglobin *in vitro*.<sup>8</sup> Similarly, the clinical conditions necessary to produce sulfhemoglobin are an oxidizing drug and either constipation or a sulfur-containing medication.<sup>131</sup> It should not be inferred that methemoglobin is an intermediary leading to sulfhemoglobinemia, since cases of congenital methemoglobinemia have not had sulfhemoglobinemia. Once formed, there is no way to rid the blood stream of sulfhemoglobin other than by actually removing blood. Treatment consists

of removing the drug and intestinal conditions causing the disorder.

#### Enterogenous Sulfhemoglobinemia

In reviewing cases of enterogenous cyanosis, one is impressed by the greater frequency of cases of sulfhemoglobinemia<sup>115, 132-142</sup> and by the predominance of constipation in these patients as compared

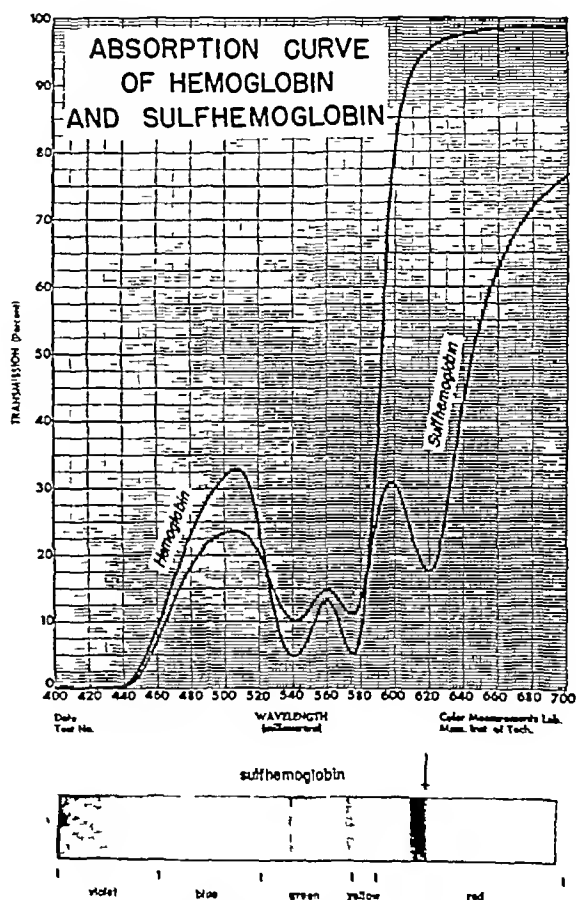

FIGURE 4 Spectrophotometric Absorption of Sulfhemoglobin

In the upper portion the percentage transmission of a solution of oxyhemoglobin is compared with that of a solution of sulfhemoglobin and hemoglobin. There is a strong absorption of the sulfhemoglobin solution at 620 millimicrons. The greater intensity of sulfhemoglobin is seen by a comparison with Figure 1. Both solutions had approximately the same amount of abnormal pigment. The absorption band of sulfhemoglobin in the red of the spectrum as seen in the hand spectroscope is shown below.

with diarrhea in patients with enterogenous methemoglobinemia. The importance of disturbed bowel function is well shown by the case of a nine-year-old boy reported by van den Bergh<sup>110</sup> with a rectal stricture and cyanosis for two years. After operation with relief of the obstruction the cyanosis disappeared. Symptoms are identical to those with enterogenous methemoglobinemia, the only clinical differentiation being the much slower rate of dis-

ing Phenylhydrazine, on the other hand acts in vivo to produce only red-cell destruction. Some drugs, — for example, the sulfonamides, — which produce predominantly methemoglobinemia, on some occasions cause extensive cell destruction.<sup>102, 103</sup> Drugs such as potassium chlorate and arsine<sup>104</sup> produce massive hemolysis but also methemoglobinemia. It appears that methemoglobin formation secondary to drugs may be regarded as a mild and reversible form of cell injury and that more severe cell damage frequently occurs and should always be looked for.

The rapidity of methemoglobin production of these various drugs is dependent upon their metabolism within the body and on their excretion. Although the effect of intravenous nitrite is expended within an hour nitrobenzene does not produce its maximum effect for twelve to fifteen hours.<sup>105</sup> The duration of action of the drug is of importance in anticipating the duration of the methemoglobinemia produced. As pointed out above, the reversion mechanism of the erythrocyte will, within a few hours, convert methemoglobin back to hemoglobin unless there is some oxidant acting in the opposing direction.

In drug-induced methemoglobinemia, the capacity of the normal red-cell reconversion mechanism may be assumed to have been exceeded, and substances that act less rapidly than this normal mechanism, as ascorbic acid does, have no place in its therapy (Fig 3).<sup>39, 43</sup> On the other hand, methylene blue is extremely effective as evidenced by numerous reports in the literature.<sup>42, 43, 91, 106</sup> Should the cyanosis not respond to methylene blue, one must suspect either that a large quantity of oxidizing substance is present, which is still able to displace the equilibrium despite the action of methylene blue, or that some other pigment, such as sulfhemoglobin is present. It has been suggested, on the basis of observations in vitro, that in some cases methemoglobin may be produced indirectly by drugs through the destruction of erythrocyte catalase, thus rendering the erythrocyte vulnerable to oxidation.<sup>107</sup> This awaits clinical verification.

#### *Enterogenous Methemoglobinemia*

Since the reports of Stokvis<sup>108</sup> and Talma<sup>109</sup> in 1902, the term enterogenous cyanosis has appeared repeatedly in the literature. Some justification for the acceptance of this as a clinical syndrome is the similarity of the case reports.<sup>110-114</sup> The patients usually have abdominal pain with diarrhea, or constipation. There are attacks of slate-blue cyanosis accompanied by headache, often shortness of breath, dizziness, collapse and syncope, van den Bergh<sup>111</sup> demonstrated nitrite-producing bacteria in the stools and nitrites in the blood of such patients. It was postulated that because of the gastrointestinal disease, there was an abnormal pro-

duction and absorption of nitrites. As pointed out by van Lier,<sup>52</sup> however, many of these patients were taking aniline derivatives for headache, and, at the time of these early reports, the capacity of these drugs to produce methemoglobinemia was not appreciated. Certainly, some of the cases may have been due to drugs, the intestinal lesions being contributory but not causative.<sup>52, 115-117</sup> In contrast to primary methemoglobinemia, anemia is frequently present in this group, and indicanuria is found. Van den Bergh noted an increase in cyanosis shortly after meals and suggested a milk diet and enemas, which resulted in improvement in several cases. Under the heading of enterogenous cyanosis cases have been reported of both methemoglobinemia and sulfhemoglobinemia, often not distinguished spectroscopically in the reports. It seems likely that the two occur together more often than reports indicate.<sup>112, 114</sup> For convenience, enterogenous methemoglobinemia and enterogenous sulfhemoglobinemia are discussed separately in this paper. It will be apparent, however, that their separation is artificial. It is not difficult to distinguish the two pigments in detailed case reports, since methemoglobin is quickly reverted to normal and therefore shows a rapidly changing blood level whereas sulfhemoglobin gradually disappears from the circulating blood over a period of two or three months.

#### *Methemoglobinemia and Hemolytic Anemia*

Two cases that have recently been observed showed both acquired hemolytic anemia and intracellular methemoglobinemia.<sup>116, 119</sup> The absence of gastrointestinal disease and of drug intake excludes the types of secondary methemoglobinemia mentioned above. The patients' erythrocytes also functioned normally in reverting methemoglobin. Although no cause has been discovered, it is conceivable that some endogenous substance is responsible for both oxidation of the hemoglobin and red-cell destruction.

#### *Therapeutic Use of Methemoglobin*

Methemoglobin is of no value in carbon monoxide poisoning but is useful in combating cyanide. Cyanide produces paralysis of tissue respiration by combining with cytochromes. It is possible to reduce its toxicity by the production of methemoglobin, for which cyanide has an even greater affinity. When methemoglobin is produced prophylactically, animals are protected against several times the lethal dose of cyanide.<sup>120-122</sup> Even when given after exposure to cyanide, methemoglobin may successfully compete with the ferricytochrome oxidase for the cyanide ion.<sup>124</sup> The usual therapeutic regime consists of 0.5 gm of sodium nitrite intravenously over five to ten minutes, followed by 25 gm of sodium thiosulfate intravenously for ten minutes. The latter combines with the cyanide to form thiocyanate, which is relatively nontoxic and is

appearance of the cyanosis. As pointed out by van Lier many patients reported had been taking aniline derivatives, which he and others<sup>52, 115, 132</sup> demonstrated to be capable of producing sulfhemoglobin in the presence of constipation.

### SUMMARY

Abnormal hemoglobin pigments may be suspected in patients by the recognizable clinical syndrome in the congenital enterogenous types, by a history of drug intake or by the very intensity of the cyanosis with minimal symptoms. The diagnosis depends on the spectroscopic identification of the abnormal pigment. Methemoglobinemia may be due to dysfunction of the normal red-cell reconversion mechanism or to conversion of hemoglobin by circulating oxidants. Treatment with methylene blue or ascorbic acid depends on the etiology of the methemoglobinemia, since ascorbic acid is effective only in congenital methemoglobinemia.

Sulfhemoglobin is formed by the action of a methemoglobin-producing drug in addition to either constipation or a sulfur-containing medication. Unlike methemoglobin, which may be reverted rapidly to hemoglobin, sulfhemoglobin once formed remains until the red cell containing it is destroyed.

dyspnea and cyanosis with nausea and vomiting but no chest pain or cough. The patient was taken immediately to the operating room. The right superficial femoral vein was ligated and divided without incident. No clot was found. The vein on the left side was exposed, found to be free of clot, and was about to be opened when the patient suddenly became cyanotic and dyspneic and died.

### DIFFERENTIAL DIAGNOSIS

DR RICHARD J. CLARK. Let us go briefly over this history again. The patient apparently had indigestion for a somewhat indefinite period, which in view of later events, may reasonably have been attributable to chronic gall-bladder disease. Seven months before entry she had a briefly described illness of three weeks' duration characterized by cough and severe left pleural pain. We wonder about the possibility of bronchopneumonia or pulmonary infarction at that time. We may question a myocardial infarction in view of later events, certainly, the description is not characteristic of any such episode although it has to be borne in mind.

She soon had a severe attack of anorexia, nausea and vomiting, following which a cholecystectomy was done. There is the helpful point that the gall bladder was found to be perforated. We know that there was definite gall-bladder disease with some element of infection and that the difficulty in the gastrointestinal system was not all secondary to cardiovascular disease. We are not told whether gallstones were present or exactly what was done whether the common duct was explored, or whether or not it was drained.

At the same point in the history cardiac enlargement was noted. This is the first indication that cardiovascular disease was present. Following operation the patient did poorly and had increasing signs of gastrointestinal disturbance and apparently some evidence of decreasing cardiac reserve. There were two short episodes of fever without chills but they are not sufficiently well described to enable us to draw any definite conclusions from them. The loose bowel movements might make one wonder if there were any involvement of the pancreas along with biliary-tract disease but there is nothing in the protocol on which I can base any such diagnosis. We are told that the gastrointestinal series was negative and that two stool examinations were negative. These factors are against any intrinsic disease of the stomach or bowel. The loss of weight is explainable on the basis of the repeated gastrointestinal upsets and anorexia.

On entry there was evidence of an abnormal heart, which appeared to be in borderline failure and also of an enlarged liver. While in the hospital the patient had an irregular fever of moderate degree. On the seventh day there occurred an episode strongly suggesting pulmonary infarction.

Subsequently, in the process of bilateral femoral-vein ligation the patient died suddenly.

The problems here are threefold. What was going on in the biliary tract, what was the cardiac lesion, and what was the terminal event? So far as the biliary tract is concerned she had had persistent gastric symptoms since the cholecystectomy and showed an enlarged liver on physical examination. We are not told whether the liver was tender or anything else regarding its character. Nothing is said about clinically detectable jaundice, and there is no report of the urinary findings. She had an abnormal biphasic van den Bergh reaction of slight degree. The cephalin-flocculation reaction was insignificant, and the prothrombin time normal. Apparently she had no serious liver disturbance. We might wonder about a residual stone in the common duct, causing intermittent biliary obstruction. If so we would expect more evidence of jaundice and also a history of some abdominal pain and colic. What about hepatic abscess of some type, secondary to biliary-tract infection? Had this been present we would have expected a more fulminating course and a higher white-cell count and a febrile reaction at the time. I rule out a malignant lesion for lack of more specific evidence. Hepatic congestion, secondary to cardiac disease, is to be considered, but I doubt this because of the long-continued symptomatology without other significant evidence of congestive failure. A low-grade ascending cholangitis, which had carried on since the time of the cholecystectomy, might explain this phase of our problem most satisfactorily.

Next to consider is the cardiac lesion. May we see the films at this point?

DR STANLEY M. WYMAN. The heart is described as grossly enlarged, the borders extending to both the right and the left, more markedly toward the left. There is a faint suggestion that the left main-stem bronchus is elevated. In the lateral view there is some prominence of the upper posterior heart border, suggesting left auricular enlargement. The heart extends well to the anterior chest wall, which makes one suspect that in addition to left ventricular enlargement there is probably right ventricular enlargement. The pulmonary vascular shadows are not definitely abnormal. There is some fluid in the left costophrenic sinus laterally. The second examination, done about a week after the first, shows an area of hazy indefinite density in the right lower-lung field, seen to lie posteriorly against the chest wall. This is the shadow interpreted as being consistent with infarct.

DR CLARK. There is some unusual prominence in the region of the pulmonary conus, is there not?

DR WYMAN. The left upper border of the heart I would not interpret as being prominent. I think the pulmonary artery is probably engorged but may be overlain by the heart shadow per se. The

### CASE 34391 .

#### PRESENTATION OF CASE

A fifty-nine-year-old woman entered the hospital because of anorexia, nausea and vomiting.

The patient was essentially well except for "indigestion" following meals until seven months before admission, when she had an illness lasting three weeks characterized by cough and severe left pleural pain. A short time following this her gall bladder was removed at a community hospital following an attack of anorexia, nausea and vomiting. The gall bladder was said to be perforated, with localized peritonitis. At that time, because of an enlarged heart and slight dyspnea on exertion, she was digitalized and continued to take the drug (one pill a day) until admission. Following operation she did not do well, being bothered by anorexia, progressive weakness, fatigue, dyspnea on exertion and afternoon ankle swelling. She had two short episodes of fever without chills and "stomach spells" occurring approximately every third day for the six months prior to admission and consisting of nausea, belching and vomiting of thick, green material. There was never any blood in the vomitus, and she never had any abdominal pain. She also noted one to three loose, watery bowel movements a day without blood, pus or cramps, the bowel habits having previously been normal and the stools formed. She lost 30 pounds of weight during the present illness.

Physical examination showed an emaciated, pale woman. The thyroid gland was not palpable. The neck veins were distended with the patient 15° above the horizontal position. The chest was emphysematous but clear. The heart seemed enlarged to percussion, the rhythm was regular, with occasional extrasystoles, and there was a Grade II systolic murmur along the left sternal border. The liver edge was felt four fingerbreadths below the costal margin.

The temperature, pulse and respirations were normal. The blood pressure was 140 systolic, 90 diastolic.

Examination of the blood revealed a red-cell count of 4,900,000, with a hemoglobin of 13 gm per 100 cc, and a white-cell count of 7500, with 74 per cent neutrophils. Two stool specimens were guaiac negative. The arm-to-tongue circulation time was 35 seconds, and the venous pressure was equivalent to 140 mm of water. An x-ray film of the chest disclosed a heart enlarged in all chambers, with a suggestion of left ventricular predominance. The lung markings were slightly increased, and there was a small amount of fluid in the left pleural sinus. An electrocardiogram showed apparent auricular fibrillation, with a rate of 85, small Q waves in Leads 2 and 3, depressed ST segments in Leads 1, 2 and CF<sub>1</sub>, flat T waves in Leads 1, 2, 3, CF<sub>1</sub> and CF<sub>2</sub>, a diphasic T wave in Lead CF<sub>1</sub>, and a tendency to low voltage. The QRS interval was 0.10 to 0.12 second. A gastrointestinal series was negative. The van den Bergh reaction was 1.4 mg per 100 cc. direct, and 1.6 mg indirect, the cephalin-flocculation test was + in twenty-four and ++ in forty-eight hours, and the prothrombin time was normal.

During the hospital stay there was an irregular fever, the temperature going as high as 101°F. During the seventh day a slight hemoptysis occurred. Fine rales were heard at the right base, and a film of the chest showed an area consistent with infarct. Heparin and dicumarol were started, but on the tenth day femoral-vein interruption was decided upon as a more permanent form of therapy. Large doses of vitamin K were given. On the following day there was a short episode of

and decided on venous ligation. We stopped the anticoagulants. On the morning of death there was an episode that seemed most likely another pulmonary infarct, so that we hurried with the venous ligation. There was no evidence at any time that she had active phlebitis in the lower extremities. We made the decision to ligate the femoral veins on a statistical basis.

DR MALLORY: Dr Means, would you like to give your opinion now or reserve it until later?

DR JAMES H. MEANS: I remember this patient very vividly and the case caused me a certain amount of emotion. I will tell you why in a moment. I took the Medical Service over the day after she came in. They had done a great deal of work on her. Dr Taylor has given an outline of what happened. They had just about disposed of the abdominal possibilities at that time, and attention was focused on the heart as probably the most important feature. I wrote, "I think the whole picture can be explained on the basis of low-grade, chronic congestive heart failure probably arteriosclerotic. I assume that is synonymous with coronary-artery disease. I suppose the indication now is to digitalize." Then I began to think more about the x-ray picture, indicating pulmonary infarction, and concluded that we ought to do something about that. Dr Dahl, as I recall, favored putting the patient on anticoagulants. She got heparin first and dicumarol afterward. We have heard so much of how to treat phlebitis that there is a great deal of confusion in the professional mind about anticoagulants versus ligation. I suppose it was because I was on dicumarol myself, having had phlebitis recently, and my medical brethren were curing me in that way, that this case was very vivid to me. We put her on these anticoagulants but I was still worried about whether she was the type of patient that should be put on anticoagulants or ligated. My thinking was conditioned a little bit by the fact that I had escaped, up to that point, getting ligation myself and I hated to wish it on her. Dr Paul D. White says here, "This is the wrong kind of patient to treat with anticoagulants." It is all right to treat a vigorous fellow like me with anticoagulants, but he advised that this bedridden cardiac patient should be ligated and I bowed to his superior wisdom. The only trouble was that we had prolonged her prothrombin time by then and we had to give her vitamin K to

shorten it. Then the surgeons took over, and she died on the table before they could ligate. I therefore think that we had grossly mismanaged this case. I felt sorry about that. I will let Dr Mallory tell us what was actually found.

DR MALLORY: Have you an opinion, Dr Zamecnik?

DR PAUL C. ZAMECNIK: I saw the patient when she first came in and was taken in by the possibility that the gastrointestinal symptoms were the most prominent feature of the history. We considered carcinoma of the stomach as a possibility. The negative gastrointestinal series then disillusioned us and caused us to pay more attention to the cardiac status.

#### CLINICAL DIAGNOSES

Pulmonary infarction  
Phlebothrombosis  
Arteriosclerotic heart disease

#### DR CLARK'S DIAGNOSES

Idiopathic myocarditis or coronary-artery disease  
Pulmonary infarcts, recent and old  
Terminal pulmonary embolism

#### ANATOMICAL DIAGNOSES

*Coronary thrombosis, recent*  
*Myocardial infarction, recent*  
*Mural thrombi, right ventricle and left auricle*  
*Pulmonary infarcts, recent and old*  
Coronary sclerosis, severe  
Cardiac hypertrophy and dilatation  
Cerebral lateral-sinus thrombosis, left

#### PATHOLOGICAL DISCUSSION

DR MALLORY: Autopsy showed no massive pulmonary embolism. There were numerous infarcts of the lung in both lower lobes of varying ages. Some of them were dense, old fibrous scars, some were of intermediate age, and one was very fresh. The heart was diffusely dilated and moderately hypertrophied. There were no valvular lesions. We found thrombi in the right ventricle and also in the left auricle. There was a large area of infarction at the apex of the heart involving the interventricular septum, and I think the right ventricular thrombi were unquestionably secondary to that. So we had an intracardiac source, as Dr

descending aorta is not remarkable. There is some calcification in the aortic arch.

DR CLARK: There is no evidence of old pleurisy on the right?

DR WYMAN: Not on the original examination. The right leaf of the diaphragm and the costophrenic angle are clear. The stomach and the duodenum appear grossly normal.

DR CLARK: There is no evidence of gallstones in the region of the gall bladder?

DR WYMAN: I do not have a film that includes the right upper quadrant adequately. I do not see any here.

DR CLARK: I gather, then, that this heart shows more generalized chamber enlargement than is ordinarily seen in coronary-artery disease. Is that correct?

DR WYMAN: Yes. It did not make me think of coronary disease primarily.

DR CLARK: The electrocardiogram as described suggests coronary disease, digitalis effect or some diffuse myocardial process. May I see a print of the tracing? This shows a normal axis with a low QRS complex in Lead 1. There are no visible P waves. The T waves throughout are low to flat. I would not consider the Q waves in Leads 2 and 3 sufficiently prominent to be significant. The QRS complexes are slightly widened.

Could this patient have had valvular heart disease? Aortic stenosis might be suggested by the Grade II systolic murmur along the left sternal border, but this alone is insufficient evidence for such a diagnosis. Viewing the x-ray films and observing suggestive left auricular enlargement we wonder about mitral disease. The murmur of mitral stenosis may be undetected, but all in all, I cannot diagnose this or any other valvular lesion.

What about hypertensive heart disease on the basis of a previously elevated blood pressure? I rule this out because of the history and the lack of any good cardiographic evidence, low voltage and absence of left-axis deviation are strong counter-evidence.

If we are to assume recurrent pulmonary infarction, could the patient have had cor pulmonale? The electrocardiogram is not in keeping, nor would this explain left-sided cardiac enlargement.

Certain rarer forms of diffuse myocardial involvement are to be considered. The generalized chamber enlargement, the continued suggestion of right-sided heart failure, the low voltage and the multiple T-wave involvement are all consistent. This patient with chronic anorexia and gastrointestinal disturbance might well have had avitaminosis, beriberi heart disease comes to mind, but in this condition the circulation time is characteristically rapid with failure, whereas here there was a prolonged circulation time. I see no good evidence for myxedema or myxedema heart in spite of the low

voltage. The distinct possibility of an idiopathic myocarditis, such as a Fiedler's, is to be seriously thought of in a situation of this type. This diagnosis is made primarily by the exclusion of other possibilities. I came here prepared to make a diagnosis of old coronary-artery disease, being influenced especially by the Q waves in Leads 2 and 3 reported in the protocol, but these we have seen to be rather insignificant. The complete lack of cardiac pain is against this diagnosis, as is the appearance of the x-ray film. I shall, therefore, put down a diffuse nonspecific myocarditis, possibly a Fiedler's, as my first bet, leaving coronary-artery disease as second choice.

Finally, let us view the pulmonary condition and terminal events. I am intrigued with the x-ray finding of fluid at the left base and none on the right. Unilateral left pleural effusion from cardiac failure has been shown to be rare unless the right pleural cavity is obliterated by adhesions. It is usually due to some local cause such as pleurisy, secondary to pulmonary infarction. Almost certainly this patient had a pulmonary infarction on the seventh hospital day and another a few days later after anticoagulant treatment, which was followed by vitamin K preparatory to venous ligation.

We are given no localizing evidence in the protocol to incriminate the legs. Obviously the Surgical Service suspected femoral phlebitis since they went ahead with ligation, and on the basis of statistics this is the most likely source for the emboli. We are told that no evidence of clot was found on opening the right vein, and this was divided. No clot was noted on the left, but death occurred before the vein was opened, presumably a clot may have slipped up from below during manipulation. A second possible source of emboli may have been from mural thrombosis in the right side of the heart, which we were told was fibrillating, but we would hardly expect such a thrombosis alone to give rise to a sudden fatal embolism. In any event I believe that we shall find evidence of multiple old and new pulmonary infarcts and that the terminal event was a massive pulmonary embolism.

DR TRACY B. MALLORY: Dr Taylor, I believe you saw this woman. Would you tell us what you thought about the case?

DR ISAAC TAYLOR: When this patient came in the question arose whether she had residual sepsis in the biliary tract or carcinoma of the stomach primarily. Because of the pulmonary infarct as described in the protocol our attention was focused in that direction. We were concerned at the same time with the treatment of congestive failure, which was brought under control. Then, as one gathers from the protocol, there was some discussion regarding how to treat this woman. She was started on anticoagulants after a couple of days on the basis of the apparently poor cardiac status, she was having a restricted life, and we changed our plans

and decided on venous ligation. We stopped the anticoagulants. On the morning of death there was an episode that seemed most likely another pulmonary infarct, so that we hurried with the venous ligation. There was no evidence at any time that she had active phlebitis in the lower extremities. We made the decision to ligate the femoral veins on a statistical basis.

DR MALLORY: Dr Means, would you like to give your opinion now or reserve it until later?

DR JAMES H. MEANS: I remember this patient very vividly, and the case caused me a certain amount of emotion. I will tell you why in a moment. I took the Medical Service over the day after she came in. They had done a great deal of work on her. Dr Taylor has given an outline of what happened. They had just about disposed of the abdominal possibilities at that time, and attention was focused on the heart as probably the most important feature. I wrote, "I think the whole picture can be explained on the basis of low-grade, chronic congestive heart failure, probably arteriosclerotic. I assume that is synonymous with coronary-artery disease. I suppose the indication now is to digitalize." Then I began to think more about the x-ray picture, indicating pulmonary infarction, and concluded that we ought to do something about that. Dr Dahl, as I recall, favored putting the patient on anticoagulants. She got heparin first and dicumarol afterward. We have heard so much of how to treat phlebitis that there is a great deal of confusion in the professional mind about anticoagulants versus ligation. I suppose it was because I was on dicumarol myself, having had phlebitis recently, and my medical brethren were curing me in that way, that this case was very vivid to me. We put her on these anticoagulants, but I was still worried about whether she was the type of patient that should be put on anticoagulants or ligated. My thinking was conditioned a little bit by the fact that I had escaped, up to that point, getting ligation myself and I hated to wish it on her. Dr Paul D. White says here, "This is the wrong kind of patient to treat with anticoagulants." It is all right to treat a vigorous fellow like me with anticoagulants, but he advised that this bedridden cardiac patient should be ligated, and I bowed to his superior wisdom. The only trouble was that we had prolonged her prothrombin time by then, and we had to give her vitamin K to

shorten it. Then the surgeons took over, and she died on the table before they could ligate. I therefore think that we had grossly mismanaged this case. I felt sorry about that. I will let Dr Mallory tell us what was actually found.

DR MALLORY: Have you an opinion, Dr Zamecnik?

DR PAUL C. ZAMECNIK: I saw the patient when she first came in and was taken in by the possibility that the gastrointestinal symptoms were the most prominent feature of the history. We considered carcinoma of the stomach as a possibility. The negative gastrointestinal series then disillusioned us and caused us to pay more attention to the cardiac status.

#### PATHOLOGICAL DISCUSSION

DR MALLORY: Autopsy showed no massive pulmonary embolism. There were numerous infarcts of the lung in both lower lobes of varying ages. Some of them were dense, old, fibrous scars, some were of intermediate age, and one was very fresh. The heart was diffusely dilated and moderately hypertrophied. There were no valvular lesions. We found thrombi in the right ventricle and also in the left auricle. There was a large area of infarction at the apex of the heart involving the interventricular septum, and I think the right ventricular thrombi were unquestionably secondary to that. So we had an intracardiac source, as Dr

Clark suggested as a remote possibility, for the pulmonary infarct

The gall bladder had been removed. We found nothing wrong with the biliary tract. The liver showed only a severe grade of chronic passive congestion. A careful search of all the ligated veins showed not the slightest trace of thrombosis above or below the ligature on either side. One other possible source of embolism is the cerebral left lateral sinus, which was extensively thrombosed, and it is conceivable, although unlikely, that the thrombus had broken loose from there. The coronary arteries showed a very old, calcified occlusion of the left descending branch, considerable sclerosis and a very fresh thrombus of the right circumflex. So death was due, I think without question, to sudden coronary occlusion, not to pulmonary embolism.

DR CLARK: How often do you see pulmonary infarcts coming from intracardiac thrombi?

DR MALLORY: We see them with significant frequency in valvular heart disease. They are quite uncommon in coronary-artery disease. Thrombi in the left ventricle, of course, are the rule in cardiac infarction, but we see them only occasionally in the right ventricle. Usually when a thrombus is present in the right ventricle it is secondary to an infarct of the interventricular septum, and thrombi will be found in both ventricles.

DR CLARK: We have recently seen 2 cases of pulmonary infarction in which the evidence was strongly suggestive of an intracardiac source of the emboli. The possibility of this mechanism is of great importance in reaching a decision regarding anticoagulant versus ligation therapy.

DR MALLORY: One can raise the point whether it is wise to give dicumarol with fresh infarction of the heart. It is quite possible that the mural thrombus, which forms over an area of infarction, tends to reinforce the cardiac wall, at that point, a process that might be prevented by the dicumarol.

DR CLARK: I have recently seen a case of myocardial infarction treated with dicumarol in which the patient died of myocardial rupture on the eighteenth day—rather later than the average rupture. Possibly the lack of mural thrombosis was the cause.

DR MEANS: Dr Clark gave a scholarly dissertation, but there is one statement that he made on which I would like to comment. He seemed to

view with some surprise the fact that nothing was found when the femoral veins were opened. I think that is common. I am sorry Dr Linton is not here but I get the impression from him that he often opens the veins when there is unquestionable thrombosis below and finds them quite empty. I do not think that the fact that they were empty is significant. Taking all the cases of pulmonary embolism with infarction, what percentage would you say come from the heart?

DR MALLORY: What would your opinion be, Dr Castleman?

DR BENJAMIN CASTLEMAN: Probably about 95 per cent.

### CASE 34392

#### PRESENTATION OF CASE

A thirty-nine-year-old salesman was admitted to the hospital because of cough and sweating.

The patient was more or less well until approximately seven months before entry, when, following a cold, he noted severe cough productive of foul sputum. The cough became progressively worse and was accompanied by night sweats and increasing dyspnea. Approximately five months after the onset of symptoms his condition became so bad that he had to stop work. He consulted a physician, who took a roentgenogram of the chest and had him admitted to a community hospital. Here he was given penicillin for ten days, after which the cough and dyspnea nearly disappeared. However, shortly before his anticipated discharge he began to have transient pain in the middle of the right side of the chest posteriorly. Since that time he had increase in cough as well as a feeling of pressure over the right side of the chest anteriorly. He never had hemoptysis.

The patient was a healthy child and had no serious illnesses. However, he stated that he had always become dyspneic on exertion and that during the past ten years he had been nervous and just "not well." Two years before entry he was found to have a duodenal ulcer by roentgenogram. He had slight abdominal pain recently and almost daily had tarry stools for an unknown length of time. He had had two "nervous breakdowns" in past years. He smoked two packages of cigarettes daily and more recently had been drinking a fair amount about every other day.

Physical examination revealed a well developed well nourished man in no acute discomfort, but having a nonproductive cough. There was an area of dullness with normal breath sounds in the mid-portion of the right side of the chest anteriorly. There was clubbing of the fingertips with questionable clubbing of the toes. The left Achilles jerk was absent.

The temperature was 98.6°F, the pulse 90, and the respirations 20 per minute.

The white-cell count was 17,600 with 75 per cent neutrophils, 2 per cent monocytes, 1 per cent eosinophils and 1 per cent basophils. The hemoglobin was 15.1 gm. The urine was normal.

An x-ray film of the chest showed an area of segmental atelectasis in the right upper lobe which involved chiefly the anterolateral portion of the lobe (Fig 1). The lung was particularly dense laterally and showed a mottled appearance more medially. A definite mass was not identified and the bronchial tree, so far as visualized on the right, was within normal limits. No definite adenopathy was observed although there was a vague density in the right paratracheal region. Comparison of the roentgenograms taken over a two-week period during the second month prior to admission showed the appearance of the lungs to be about the same, although in the present examination the lateral density was slightly greater. A gastrointestinal series was negative. There was no evidence of a filling defect or ulcer.

Three days after admission bronchoscopy was done with a report of "considerable mucopurulent sputum from the right upper lobe and moderate inflammatory changes in that orifice, mild changes in the rest of the right main bronchus, and a normal carina and left bronchial tree — the findings are consistent with inflammatory disease of the right upper lobe, no neoplasm is seen."

Smears were taken by bronchial lavage of the right main bronchus for cytologic examination. These were reported negative.

A culture of sputum was reported to have alpha-hemolytic streptococci as the predominating organism and was negative for beta streptococcus and pneumococcus. No acid-fast bacilli were seen in the sputum.

The highest temperature recorded during the week after admission was 99°F. Usually it was normal or subnormal.

On the ninth hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR ALLEN G BRALEY: Let us look at the x-ray films.

DR STANLEY M WYMAN: The minor septum is arched somewhat upward and is particularly well seen in the lateral view, having a rather high bend.

FIGURE 1

posteriorly and laterally. There is an area of rather indefinite density in this portion of the upper lobe, the density extending posteriorly and toward the hilus. There is a suggestion of a very poorly defined section of central rarefaction in this area, measuring about 3 cm in diameter. This cannot be identified in the lateral view because the film is not adequately exposed. The bronchus to the right upper lobe can be seen for a short distance and appears grossly normal. There is no appreciable fluid in either pleural cavity, but there is a suggestion of some pleural reaction overlying the right upper lobe laterally. I am not much impressed by the density described in the right mediastinum laterally. The examination on the gastrointestinal series is reported as being negative and I cannot see any gross disease. The duodenal cap is not well outlined.

DR BRAILEY Why do you say atelectasis? Why not just consolidation?

DR WYMAN The position of the septum indicates some collapse of a portion of the upper lobe. The septum is displaced upward, out of the normal situation.

DR BRAILEY Is there any x-ray evidence to indicate whether or not air is going into that part of the lobe?

DR WYMAN No x-ray evidence, except that there is atelectasis. Presumably there is peripheral disease, whether or not it is due to bronchial plugging, I cannot say.

DR BRAILEY This process is in the upper lobe?

DR WYMAN Yes, entirely in the upper lobe.

DR BRAILEY The problem presented by this patient is defined rather sharply in the history. He was an unstable, ill adjusted person, to be sure, but he had an organic disease process as well, which appeared to be confined to the chest—in fact, to the anterolateral division of the right main bronchus. The evidence given implies an obstructive lesion of the bronchus in question, with atelectasis and some degree of infection distal thereto. Such an obstruction might be produced by any one of three things: foreign body, an inflammatory process or neoplasm. Foreign body does not need to be seriously considered, I think. An adult who has inhaled a foreign body will surely be able to give a vivid account of the time, place and circumstances under which it occurred.

The question that gives this history a lively interest is whether the bronchial obstruction was inflammatory or neoplastic, or, more exactly, whether it was tuberculous or neoplastic, since the odds are overwhelming that if the stenosis was the result of inflammation, the inflammation was endobronchial tuberculosis. What scraps of evidence in favor of tuberculosis can we dig up? At thirty-nine years the patient was a relatively young man, and furthermore he offered the information that for ten years he had not considered himself really well. Perhaps he was trying to describe the unexplained fatigability and lassitude that are often early signs of tuberculosis. The x-ray picture is not typical of tuberculosis, but neither is it inconsistent.

Do you agree that it is not inconsistent with tuberculosis, Dr Wyman?

DR WYMAN I agree, it is not inconsistent with it.

DR BRAILEY But certainly if he had acid fast bacilli of any considerable duration, the disease was an unusually benign and smoldering affair. He had had no hemoptysis. He seems to have had little fever. Nothing is said of weight loss, and finally no acid-fast bacilli were seen in the sputum. We are not told whether this was a single routine examination or whether the sputum was concentrated. Nevertheless, acid-fast bacilli are apt to be found easily in the sputum of patients with endobronchial disease and, therefore, some importance must be attached to the statement that they were not found in this case even though the search may have been casual.

In weighing the evidence for neoplasm one should consider adenoma first. Ten per cent of all pulmonary tumors are adenomas of the bronchi, and the great majority occur in persons under forty years of age. They typically produce obstruction with drowned lung upstream from the dam. On the other hand, they are prone to bleed, and this man raised no blood. Still worse, they occur almost exclusively in main-stem bronchi and are readily seen by the bronchoscopist whereas the lesion in this case could not be seen.

The only other obstructive lesion we need to consider seriously is carcinoma of the bronchus. It is the commonest pulmonary tumor, although it is true that only 10 to 15 per cent of such carcinomas occur in men as young as this patient. It usually arises in main-stem bronchi, but 25 per cent develop sufficiently remote from the trachea not to be visible by bronchoscope. The presenting symptom is characteristically a harassing and persistent cough, followed by dyspnea and later other signs, such as pain, hemoptysis and weight loss. This patient had clubbing of the fingers. The physiology of clubbing is still poorly understood, but it is a fact that clubbing frequently occurs in persons with carcinoma of the bronchus whereas it is a rather rare sign in tuberculosis. Against cancer we have a negative cytologic smear, but I do not believe that we can allow ourselves much reassurance on that account.

Judgment is difficult as Hippocrates warned. I would like a much more careful search for tubercle bacilli, but I am going to assume that the patient did not have tuberculosis. Obviously he was a

rather neurotic person with a history of "nervous breakdowns," requiring forty cigarettes a day and capable of describing normal stools as tarry. I think his alleged ill health of ten years' duration was only evidence of maladjustment. I think it is better judgment to guess that he had a cancer of the bronchus of a few months' duration, which produced early obstruction and which should have been easily resectable.

DR WYMAN: Could this have been purely an inflammatory process such as a solitary lung abscess, Dr Brailey?

DR BRAILEY: I do not see why not. You did not say he had an abscess until just now. Furthermore, an abscess certainly could arise *de novo* with no obvious excuse. But the film suggests that the bronchus was plugged and that the abscess was secondary to plugging. I think the important thing is not whether the patient had an abscess but why the bronchus was stenosed.

DR WYMAN: From the x-ray point of view this could be a peripheral tumor or inflammation. The area of rarefaction could be an abscess cavity or cavitation in tumor. It is poorly seen on these films, however.

DR DONALD S. KING: As we watched this patient preoperatively we came to the conclusion that the process in the lung was due to a chronic nontuberculous infection rather than tuberculosis or infection secondary to a bronchial tumor. At one time he had had definite foul sputum, but this persisted for only a short time and in general the cough and sputum became less troublesome rather than more so. Besides this we had the evidence of a negative bronchoscopy and a negative examination of bronchial secretion for tumor cells. Nevertheless, the x-ray densities persisted, and we believed that exploratory operation was definitely indicated.

## CLINICAL DIAGNOSIS

Chronic nontuberculous pulmonary infection

## DR BRAILEY'S DIAGNOSIS

Carcinoma of bronchus

## ANATOMICAL DIAGNOSIS

*Lung abscess*

## PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN: The surgeon removed the right upper lobe. On cutting through the lobe it was found to be slightly smaller than normal and very heavy, with very little air anywhere in the lobe. On section, there was a collapsed cavity 7 cm in diameter, and the surrounding area was atelectatic. Microscopical examination showed no evidence of tumor but a chronic inflammatory process, the center of which showed acute inflammation with necrosis. Surrounding it was a great deal of necrosis with destruction of the alveolar walls. So I think we have to assume that this was a chronic lung abscess, etiology undetermined.

DR BRAILEY: It started out with upper respiratory infection?

DR CASTLEMAN: Yes.

DR KING: Because the patient was of a very nervous disposition we anticipated a stormy convalescence but were happily surprised to find that he had very little postoperative difficulty and could be discharged just a little less than two weeks after the lobectomy. He was still worried about all sorts of extrapulmonary symptoms, but I believe that the pulmonary condition has been cured.

## POPULATION TRENDS

ENGLAND has become so alarmed over her trend toward an aging and declining population, that four years ago the Coalition Government appointed a Royal Commission to study the problem. For sixty years the birth rate had been falling, but also the country had known demoralizing unemployment, resulting in a paradoxical and disturbing state of affairs. Concerned as the kingdom was over its declining population it could not adequately care for what it had.

Immediately on appointment of the Commission, according to *The Lancet*\* the birth rate suddenly rose "impishly and awkwardly" to confuse the planners and becloud the issue. This rise was not sustained. The rate again started downward, per-

haps because the Government had given the family man a woefully inadequate relief in taxes to compensate for his increased expenses.

In general, reactions toward population trends are hardly consistent with the apparent facts. Politicians, with a nearly pathologic fervor, crave large populations, viewing them, apparently, almost in the light of standing armies despite the inevitable consequences, sooner or later, of unemployment, poverty and discontent. Yet even from a military standpoint large populations are not necessarily the important factor in a nation's greatness. Certainly in some of the countries of Asia, the most heavily populated in the world, numbers have proved to be no asset from any angle.

This much must be conceded. Declining population levels are frequently a sign of decadence. They mark the turning point of nations that have passed their peak in expansion, in strength and in character, and are substituting for a waning national ambition an attempt—that has always proved eventually vain—to consolidate their gains, rest on their laurels, withdraw behind their defenses and exist in comfort and security.

The aggressive behavior that results in wars between nations represents to many persons an intolerably nationalistic attitude, but the fact remains that when a species or a nation or a person is forward bound and headed toward some destined goal, aggressiveness, and in the instance of the first two, growth, are of the essence of their strength.

Population, however, while it tends to increase as a nation struggles into the sun, does not provide the best answer to the problem of prolonged survival. The spirit of a people is more important than its numbers. Population trends are important only as they indicate a nation's spirit of survival, or its loss. And without that spirit no economy, however well planned, can long be successful.

## CENTENNIAL OF THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

ELSEWHERE in this issue of the *Journal* attention is called to the centennial celebration of the founding of the Medical Society of the State of Pennsylvania in Philadelphia from October 3 to 7

\*Leading Article "Population policy," *Lancet* 1 717 1948

An interesting scientific and social program has been arranged for the meeting

The organization of the society followed close on the heels of the first meeting of the American Medical Association in 1847. In December of that year representatives of the Chester County Medical Society, believing that physicians should organize on a state-wide basis, met in Lancaster, where the following resolution, proposed by Dr Wilmer Worthington, later president of the State Society, was adopted:

Whereas no State Medical Society exists in Pennsylvania and believing that such an institution would greatly contribute to the advancement of medical knowledge within its bounds,

Therefore *Resolved* that it is expedient to hold a convention at such time and place as may be hereafter agreed upon to effect such permanent organization as may be deemed best suited to accomplish the object in view.

The Lancaster County Medical Society concurred in this resolution and in April 1848 gathered the men who organized the Medical Society of the State of Pennsylvania.

The *Journal* extends heartiest congratulations to the Pennsylvania physicians and expresses the hope that the centennial celebration will be as successful and pleasant as the fiftieth anniversary in 1898 for which it had been announced that Lancaster County Medical Society was prepared to 'set out barrels and barrels of pretzels.'

PUBLIC HEALTH AND THE DISEASES OF OLD AGE

ONE of the recent Saturday morning sessions of the Health Forum conducted by the Harvard School of Public Health was devoted to a discussion of public health and diseases of old age by Louis I. Dublin, chief statistician for the Metropolitan Life Insurance Company.\* In his address Dr Dublin pointed out the marked change that the mortality picture in this country has undergone since the turn of the century. The basic shift has been in the direction

of greatly increasing the importance of the diseases of later life. These changes he noted have been brought about by two major developments: the extraordinary success achieved by medical science and public-health administration in the control of infectious diseases and the progressive aging of the population. The indications are that these trends will continue.

Dr Dublin called attention to the striking change that the age structure of the population is undergoing. In 1900 only 4.1 per cent of the population of this country was sixty-five years or older; by 1940 the proportion increased to 6.8 per cent and it is estimated that by 1960 more than 9 per cent and by the turn of the century more than 15 per cent of the population will be in this old-age bracket. The actual numbers involved are even more impressive. In 1900 there were about 3,000,000 people in the United States who were sixty-five or older; in 1940 the number in this age group increased to nearly 9,000,000 and by 1960 their total is expected to reach 14,000,000 and by the end of the century 21,500,000.

Accompanying this change in age distribution of population there are parallel changes in the ranking of the leading causes of death. In 1900 the first ten causes of death were tuberculosis, pneumonia, diarrhea and enteritis, heart disease, nephritis, accidents and violence, cerebral hemorrhage, cancer, bronchitis and diphtheria, in that order. By 1940 diseases of the heart, cancer, accidents and violence, cerebral hemorrhage and nephritis were the five leading causes of death and pneumonia, tuberculosis, premature birth, diabetes and arteriosclerosis followed in that order. Thus of the ten principal causes of death at present only one is concentrated in early life; the others either show a heavy concentration in later life or have the highest death rates in the older age groups.

The data that Dr Dublin brought out indicate the need for a reorientation in the point of view and in the activities of social and welfare agencies, health officers and physicians to meet the changing needs of their communities. The public-health and medical professions, he believes, have largely solved the major problems of sanitation and communicable-disease control and should now be prepared to

\*Public health and diseases of old age (Summary). *Statist Bull Met-Life Ins Co* 9:1 1948.

wrestle with the more difficult problems of conserving life and health in the middle-aged and older people. The major concern should be with the cardiovascular-renal diseases, cancer and diabetes since the greatest amount of ill health is due to these conditions. There are a number of other causes of sickness and death among older people that he believes should merit greater attention, these include tuberculosis, pneumonia, mental diseases, nutritional diseases and accidents. Dr. Dublin suggests that the efforts of health departments, private physicians and organized medical groups and voluntary health and safety agencies should be co-ordinated at the local level. The person most suited to take the primary responsibility of co-ordinating these efforts is the health officer, who should be the logical leader in developing effective health service for his community.

## PR

PUBLIC relations and the practice of medicine have practically always been nearly synonymous, although their affinity had not been officially recognized until the term "public relations" was recently popularized. The invention of the term and the recognition of its importance have resulted from modern attempts at the orderly organization of all human activities where one group of persons has dealings with another.

Then it was discovered that the old personal relations of the physician with his public were suffering considerably from neglect on both sides and that attempts at repair must be made forthwith.

Certainly considerable elements of the public that have never known and consequently could scarcely appreciate the relations between the good family physician and his practice have found that they did not know how to obtain satisfactory medical advice. Too many physicians have been unconscious of or indifferent to the cordial and reciprocal relations that may and should exist between physician and patient. It is unfortunate but consistent with modern methods that repairs must be made on an assembly-line pattern.

As a result of this growing need in a world where each man looks askance at his neighbor the first

national medical public relations conference ever to be held will meet in St. Louis on November 27 to tackle six common objectives confronting the medical profession. The conference is under the sponsorship of the Secretary's office of the American Medical Association, its theme is "Shooting at Common Targets in Medical Public Relations," and qualified speakers will talk on such subjects as "The Public Speaks on Health," "What Public Relations Did for Us," and "Yes, the Profession needs PR."

The six major social issues that will be tackled are selling the need of public relations to state-medical society members, encouraging wider use of medical prepayment plans, setting up workable systems for handling night calls, the rebate problem, developing good will with labor, farm, industrial and co-op groups, and co-operating with health agencies.

If, out of the expected welter of slogans, catch phrases, maxims, speech making and general escape of steam in all directions can come the idea that man, and particularly the physician, is after all his brother's keeper, much good will come of the conference.

## MASSACHUSETTS MEDICAL SOCIETY

### DEATHS

APPEL — Bernard H. Appel, M.D., of Brighton, died on September 3. He was in his fiftieth year.

Dr. Appel received his degree from Tufts College Medical School in 1922. He was associate visiting physician at Beth Israel Hospital.

His widow, a son and a daughter survive.

DENNY — Francis P. Denny, M.D., of Brookline, died on September 6. He was in his eightieth year.

Dr. Denny received his degree from Harvard Medical School in 1895. He was chairman of the Advisory Council of Public Health and formerly health director in New London, New Hampshire, and was a member of the New England Pediatric Society and a fellow of the American Medical Association.

His widow survives.

MYERSON — Abraham Myerson, M.D., of Brookline, died on September 3. He was in his sixty-seventh year.

Dr. Myerson received his degree from Tufts College Medical School in 1908. He was professor emeritus of neurology at Tufts College Medical School and formerly clinical professor of psychiatry at Harvard Medical School. He was director of research at Boston State Hospital and was a member of the American Neurological Association, American Psychiatric Association, New England Society of Psychiatry and American Psychopathological Association and a fellow of the American Medical Association.

His widow, two sons and a daughter survive.

## RICHARD PEARSON STRONG (1872-1948)

Richard Pearson Strong was born at Fortress Monroe, Virginia, the son of Colonel Richard Pearson Strong. Throughout his life he exemplified the Army tradition of devotion to duty, whatever he undertook was carried through to the best of his ability. He was never discouraged by difficulties, and he never spared himself when his services were needed, the pre-eminent success of his medical career being due in large measure to these qualities. They were supplemented, however, by good basic training as a member of the first medical class to graduate from Johns Hopkins University School of Medicine and by postgraduate work in Berlin.

Strong's career began as a surgeon in the regular Army during the Spanish-American War. He organized medical research for the Army in the Philippine Islands, serving until 1902. Thereafter, until 1913, he directed the Biological Laboratory of the Bureau of Science in Manila. During this period, he personally conducted a series of important studies on dysentery, plague, cholera and other diseases that made him an international figure in the field of tropical medicine. When the terrible epidemic of pneumonic plague swept northern China in the winter of 1911, Strong was the American delegate to the International Plague Conference, which met in Peking. He and his associate, Teague, went into the stricken area to conduct experiments and to perform autopsies, working in unheated rooms during extremely cold weather, where they were exposed to infection of the most deadly character.

Strong was called to Harvard Medical School in 1913 to become its first professor of tropical medicine. He held this position until 1938, when he became professor emeritus.

From time to time, Strong led expeditions to tropical countries to gather data and to study tropical diseases in their natural habitat. Important among these expeditions were those to Peru in 1913, to the Amazon Basin in connection with

the Seventh Hamilton Rice Expedition in 1925, to Liberia and the Belgian Congo in 1926 and 1927, to Guatemala in 1931 and 1932 and again to the Belgian Congo in 1934.

So great was the demand for Strong's services that he was repeatedly granted leave of absence from his University duties. He combated the epidemic of typhus fever that raged in Serbia in 1915,

he demonstrated the mode of transmission of trench fever during World War I, he organized the Cannes Conference for the Red Cross in 1919 and assumed leadership of the medical section of the League of Red Cross Societies in Geneva in 1919 and 1920.

After retirement from his professorship at Harvard and at the request of his old friend Admiral Stitt, Strong largely rewrote Stitt's textbook on tropical diseases.

The United States had scarcely entered World War II when Strong was called upon to organize and conduct teaching in tropical medicine at the Army Medical School in Washington. Class

after class passed through his hands at intervals of six weeks until the war was over. The acclaim that he received for this teaching and the affectionate admiration that he inspired in the hearts of those who took the courses and in his associates as well testify to the excellence and the value of his contribution. This Washington assignment may be considered as the crowning achievement of his career.

Dr Strong received many honors from the United States Government, from medical institutions, and from other scientific bodies and universities in the United States, as well as from foreign governments. He died on July 4, 1948, after a protracted and painful illness. His courage and sweetness while in pain were an inspiration to those who were privileged to see him during this period. He will live long in the hearts of his many devoted friends and his influence will outlive them all.

## BOSTON MEDICAL LIBRARY

## IMPORTANT REFERENCE WORKS

The Library, aware of its responsibility to the medical profession of Massachusetts and northern New England, is particularly interested in procuring large or expensive reference works and especially the collected works of famous physicians. In this connection the following works have recently been acquired:

*Traité de médecine* Paris, 1948-1949 To be published in seventeen volumes. Eight volumes have been issued to date, covering the subjects of infectious diseases, avitaminoses, intoxications and anaphylaxis, respiratory diseases, diseases of the digestive tract, liver and pancreas and the endocrine glands.

Curry, Manfred *Bioklimatik Die Steuerung des gesunden und kranken Organismus durch die Atmosphäre* Two volumes Riederau, 1946. This is a monumental work on the relation of climate and weather to man in health and disease.

Gradwohl, R. B. H. *Clinical Laboratory Methods and Diagnosis* Fourth edition. Three volumes. St. Louis, 1948. This new edition has been greatly expanded. Volume III comprises the material on the subjects of parasitology and tropical medicine. The previous edition was issued in two volumes.

Fuchs, Adalbert *Die Erkrankungen des Augenhintergrundes* Wien, 1943. Illustrated with forty-four excellent color plates.

Freud, Sigmund *Gesammelte Schriften* Eleven volumes. Leipzig, 1925-1928. The collected works of this important pioneer in psychoanalysis.

Purkyne, Jan Evangelista *Sebrane spisy* Four volumes. Prague, 1919-1941. The collected works of a famous physiologist noted for his work on ophthalmoscopy. He made observations on the interior and background of the eye at least twenty-five years before Helmholtz.

## NOTE

The Library has recently received a handsome English grandfather's clock from the executors of Mrs. Mary Fifield King. It was presented to the Library in 1897 by Mrs. William B. C. Fifield after the death of Dr. Fifield but was to remain in the possession of Mrs. King as long as she desired. The clock was constructed by Henry Thornton, of London, a member of the Clock Makers Company, in 1699. The date of manufacture was about 1700. After cleaning it will be placed in or near the Fifield Room.

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

## CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS

The October schedule for Consultation Clinics for Crippled Children in Massachusetts under the provisions of the Social Security Act follows:

CLINIC	DATE	CLINIC CONSULTANT
Lowell	October 1	Albert H. Brewster
Salem	October 4	Paul W. Hugenberger
Haverhill	October 6	William T. Green
Greenfield	October 11	Charles L. Sturdevant
Brockton	October 14	George W. Van Gorder
Worcester	October 15	John W. O'Meara
Gardner	October 19	Carter R. Rowe
Springfield	October 19	Garry deN. Hough, Jr.
Pittsfield	October 20	Frank A. Slowick
Fall River	October 25	David S. Gnee
Hyannis	October 28	Paul L. Norton

Physicians referring new patients to clinics should get in touch with the district health officer to make appointments. Patients are seen by appointment only.

## MISCELLANY

## GRAFTON STATE HOSPITAL

Dr. Harlan L. Paine resigned his position as superintendent of the Grafton State Hospital on September 15, 1948, after completing 27 years' service on that date. He will assume the superintendency of the Channing Sanitarium, Inc., in Wellesley, Massachusetts.

## QUALIFICATIONS FOR SPECIALIST'S RATING IN PREVENTIVE MEDICINE

Applications from medical officers of the armed forces who want to be certified as specialists in preventive medicine may now be submitted to the Interim Board of Preventive Medicine, according to Department of the Army Circular No. 234, dated August 5, 1948. The circular also outlines the qualifications required of applicants and lists the items to be included in the applications. Written and oral examinations will be held during the fall of 1948 or the spring of 1949.

The circular also announces that the first group of officers to be certified will include those selected by the board as having "considerable experience and a long record of distinguished service in responsible preventive medicine or public health positions." For this first group, formal training and supervised experience requirements, as well as written examination, will be waived.

Examinations and certification will be administered by the Interim Board of Preventive Medicine, formed early this year by joint action of the Surgeons General of the Army, Navy, and United States Public Health Service in anticipation of the formation of an American Specialty Board in this field by the Advisory Board for Medical Specialties of the American Medical Association. The Interim Board was set up to serve only the three services.

Prerequisite qualifications include, among other things, membership in the American Medical Association, graduation from a medical school and internship in a hospital approved by the Council of Medical Education and Hospitals of the American Medical Association or by the Army or Navy, the degree of Master of Public Health or its equivalent, and both supervised experience and experience in a position of responsibility in the field of public health or preventive medicine.

## CORRESPONDENCE

## DRUGS IN HYPERTHYROIDISM

To the Editor An alarming statement subject to considerable unfavorable notoriety is made in an editorial in the August 5 issue of the *Journal* entitled "The Thyroid Nodule." This statement is quoted in its entirety "There is also the possibility that the drugs used in the treatment of hyperthyroidism may in some cases precipitate the development of carcinoma."

In view of the large number of patients who are receiving medical treatment of the thyroid gland, either definitively or preoperatively, this statement has widespread implications and deserves amplification and verification. If there is supportive evidence that certain drugs used in thyroid therapy are carcinogenic, they should be specifically mentioned. This type of aspersion may create unnecessary alarm for both patients and physicians and should be either adequately explained or withdrawn.

SEYMOUR B. LONDON, M.D.

ROSE E. LONDON, M.D.

Miami Beach 39, Florida

Note Payne, Crane and Price, in a study entitled "Thiouracil and Carcinoma of the Thyroid" (*Surgery* 22:496-501, 1947), reported a carcinoma of the thyroid gland developing in a patient receiving thiouracil in preparation for operation for hyperthyroidism. In unpublished data Bowler presents a similar case. Broders and Parkhill, in an article entitled "Diffuse and Adenomatous Goiter and Goiter Induced by Various Agents" (*Surgery* 16:633-646, 1944), describe the histology of thiouracil-induced goiters as characterized by cellular hyperplasia with marked mitotic activity, suggestive of carcinoma. In his study on "Tumours of the Thyroid Produced by 2-Acetyl-Amino-Fluorine and Allyl-Thiourea" (*Brit J Exper Path* 25:90-95, 1944), Bielchowsky produced thyroid carcinoma in animals by the use of allyl-thiourea in conjunction with the carcinogen 2-acetyl-amino-fluorine, but was unable to cause thyroid carcinoma by the use of the carcinogen alone. Purves and Griesbach produced thyroid tumors and some cancers in rats treated with thiourea (*Brit J Exper Path* 27:294-297, 1946). They stated "We believe that the production of these thyroid tumors is due, not to any direct carcinogenic action of the thiourea administered, but rather to the excessive and prolonged stimulation of the thyroid epithelium."

It is evident that thiourea derivatives result in extensive hyperplasia with mitoses in man as well as in experimental animals. In animals, adenomas arise as a result of the hyperplasias, as pointed out by Hellwig in a study entitled "Thyroid Adenoma in Experimental Animals" (*Am J Cancer* 23:550-555, 1935). The relation of adenomas to carcinoma development is rather widely accepted.—En

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Progress in Clinical Medicine*. By various authors. Edited by Raymond Daley, M.A., M.D. (Camb.), M.R.C.P., and Henry G. Miller, M.D. (Durh.), M.R.C.P., D.P.M. 8°, cloth 356 pp., with 22 illustrations and 15 plates. New York: Grune and Stratton, 1948. \$6.00.

Twelve specialists in their particular fields have collaborated in writing this report of progress in certain clinical subjects. The subjects discussed comprise the control of infections, venereal diseases, tropical medicine, gastrointestinal disorders including liver diseases, metabolic disorders, cardiovascular and renal diseases, blood diseases, diseases of the chest and nervous system, endocrine disorders, psychosomatic medicine and chronic rheumatism. Each subject is documented with a list of selected references. A good index

concludes the volume. The printing and type are good. The heavy, coated paper is unnecessary since all plates are inserts. The glare from the paper is distressing and fatiguing to the eyes. The book is recommended for all medical libraries as a reference source.

*Foundations of Neuropsychiatry*. By Stanley Cobb, M.D., Bullard Professor of Neuropathology, Harvard Medical School, and psychiatrist in chief, Massachusetts General Hospital. Fourth revised and enlarged edition of the work formerly known as *A Preface to Nervous Disease*. 8°, cloth, 260 pp. Baltimore: The Williams and Wilkins Company, 1948. \$2.50.

In this fourth edition of a popular standard manual, first published in 1936 and largely amplified in succeeding editions, the author has made corrections in all sections to keep the text up to date, and new references have been added where considered pertinent. The manual is written for students and practitioners with the object of giving the facts and correlations needed to understand the simpler workings of the central nervous system. The book is well published and is recommended for all medical libraries.

*A Synopsis of Anesthesia*. By J. Alfred Lee, M.R.C.S., L.R.C.P., M.M.S.A., D.A., consultant anesthetist to Southend General Hospital and Southend Municipal Hospital, Rockford, anesthetist to Tilbury Hospital, Runwell Hospital, East Ham Memorial Hospital and Essex County Council, assistant anesthetist to King George Hospital, Ilford. 12°, cloth, 254 pp., with 42 illustrations. Baltimore: The Williams and Wilkins Company, 1947. \$4.00.

This small manual, written for the student, the resident anesthetist and the general practitioner, is a summary of current teaching and practice, and is not intended to displace the large works on the subject. The text covers the whole field of anesthesia and is well arranged. A short first chapter is devoted to notes on history, including a chronology of important dates from 1771 to 1940. The text was printed in England and the sheets bound in the United States. The work reflects the best English practice. It should be in all anesthesia collections.

*The Aseptic Treatment of Wounds*. By Carl W. Walter, M.D., assistant professor of surgery, Harvard Medical School, and senior associate in surgery, Peter Bent Brigham Hospital. 4°, cloth, 372 pp., with 255 illustrations by Mildred B. Coddington, A.M., surgical artist, Peter Bent Brigham Hospital. New York: The Macmillan Company, 1948. \$9.00.

This monograph has been written primarily as a text for medical-school courses in surgical technic, but it should prove valuable to operating-room nurses and attendants, manufacturers and distributors of surgical apparatus and to technologists and craftsmen who have to do with such apparatus. The technic described is that elaborated at the Peter Bent Brigham Hospital at Boston during the past twelve years, and reflects the surgical philosophy of Harvey Cushing and Elliott C. Cutler. The author expresses the thought that because of the wide use of chemotherapy surgeons are becoming careless and not following a rigid standardized technic so essential to clean wound healing. Therefore, he has attempted to correlate the existing knowledge on the aseptic treatment of wounds for the general benefit of the operating surgeon and his assistants and technicians. The material is well organized and the text well written. The subjects of disinfection and sterilization in all their aspects are covered thoroughly. There are chapters on chemical and physical destruction of bacteria, air-borne contamination, operating-room technic, preparation of parenteral fluids, blood and plasma facilities, central-supply-room technic, hospital infection of wounds and the control of communicable disease. The illustrations carry a large part of the book and are excellent in their delineation of the points portrayed. The selected references are printed as footnotes to the text. A good index concludes the volume. The printing is well done with an excellent type, on good, light nonglare paper. The book is delightful to read and is a credit to the publisher. It is recommended for all medical-school and nursing-school libraries and to all persons interested in surgery.

*Taking the Cure The patient's approach to tuberculosis* By Robert G Lovell, M.D., University Hospital, University of Michigan, Ann Arbor 12<sup>o</sup>, cloth, 93 pp., with illustrations by Donald Gooch New York The Macmillan Company, 1948 \$2.00

This small book has been written for the new tuberculosis patient and contains much sensible practical information. There is a chapter on tuberculosis written for the layman who desires medical information about the disease. The book is well published and easy to read. It should be available to patients and their families.

## NOTICES

### ANNOUNCEMENT

Dr Richard N Abbott announces the opening of his office for the practice of pediatrics at 15 Winnemav Street, Natick.

### FBI

The Federal Bureau of Investigation announces that the fugitive from justice concerning whom a notice was published in the *Journal* of August 12, 1948, has been apprehended and is now in custody.

### SUFFOLK CENSORS' MEETING

The censors of the Suffolk District Medical Society will meet for the examination of candidates at the Boston Medical Library, 8 Fenway, Boston, on Thursday, December 2, at 4:00 p.m.

### HAMPDEN DISTRICT MEDICAL SOCIETY

The Program Committee of the Hampden District Medical Society has arranged for the following meetings in 1948-1949. On November 30, 1948, at 8:30 p.m., in the Academy of Medicine, Springfield, Dr Grantley W Taylor will speak on the subject "Carcinoma of the Breast." On January 25, 1949, at 8:30 p.m., in the Academy of Medicine, Springfield, Dr John Rock will speak on the subject "A Review of the Sterility Problem." And on April 26, 1949, at 6:00 p.m., in the Hotel Highland, Springfield (dinner meeting), Dr Douglas T Davidson will speak on the subject "Convulsive Disorders."

### NEW YORK ACADEMY OF MEDICINE

The Twenty-First Graduate Fortnight of the New York Academy of Medicine will be held October 4 through October 15, the subject being "Advances in Therapy." The program includes morning panel discussions, afternoon clinics, evening lectures, scientific exhibits and demonstrations.

A physician who is not a fellow of the Academy may obtain registration by sending his name and address, accompanied by a check for six dollars, to the New York Academy of Medicine, 2 East 103rd Street, New York 29, New York.

### AMERICAN BOARD OF OPHTHALMOLOGY

The American Board of Ophthalmology will hold practical examinations in San Francisco from March 21-24, in New York City from June 11-15, in St. Louis from October 15-19 and in Boston in December, 1949. A written qualifying test will be held in January, 1949. Applications for the 1950 written qualifying test are now being accepted.

Candidates for the certificate of the American Board of Ophthalmology are accepted for examination on the evidence of a Written Qualifying Test. These tests are held annually in various parts of the United States.

Registration is already closed for the next test to be given in January 1949.

Applications are now being accepted for the 1950 Written Test. They will be considered in order of receipt until the quota is filled.

A supplementary list of diplomates from January, 1948, to January, 1949, will be sent without charge to all purchasers of the Board's *Directory*. This supplementary material is arranged alphabetically and geographically. No biographical material is included.

### MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

The centennial celebration of the Medical Society of the State of Pennsylvania will be held in Philadelphia from October 3 to 7. The meeting will consist of scientific sessions at the University of Pennsylvania, social gatherings at the Bellevue-Stratford Hotel and clinicopathological conferences.

Further information regarding the program may be obtained from Dr Walter F Donaldson, secretary-treasurer, Medical Society of the State of Pennsylvania, 8104 Jenkins Arcade, Pittsburgh 22, Pennsylvania.

### VAN METER PRIZE AWARD

The American Goutier Association again offers the Van Meter Prize Award of three hundred dollars and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. Provided essays of sufficient merit are presented in competition, the award will be made at the annual meeting of the association, which will be held in Madison, Wisconsin, on May 26, 27 and 28, 1949.

The competing essays may cover either clinical or research investigations, should not exceed three thousand words in length and must be presented in English, and a typewritten double-spaced copy sent to the corresponding secretary, Dr T C Davison, 207 Doctors' Building, Atlanta 3, Georgia, not later than March 15, 1949. The committee, who will review the manuscripts, is composed of men well qualified to judge the merits of the competing essays.

A place will be reserved on the program of the annual meeting for presentation of the winning essay by the author if it is possible for him to attend. The essay will be published in the annual *Proceedings* of the association. This will not prevent its further publication, however, in any journal selected by the author.

### ARMY MEDICAL RESIDENT TRAINING PROGRAM

Applications for the Military Resident Training Program (in Army general hospitals) are currently being received in the Office of the Surgeon General, United States Army. Under this training program any physician who qualifies for and accepts a commission in the Regular Army Medical Corps will be given the opportunity of competing for an approved residency in the field of his choice.

Medical specialty training available for newly commissioned officers under this program is as follows: a limited number of senior residencies in thoracic surgery, orthopedics, pulmonary diseases, pathology, ophthalmology and physical medicine, a limited number of residencies in orthopedics, pathology and physical medicine, a limited number of assistant residencies in obstetrics, urology, thoracic surgery, dermatology and pediatrics, and a substantial number of assistant residencies in anesthesia, general surgery, orthopedics, internal medicine, psychiatry, pathology, ophthalmology, otolaryngology, radiology, physical medicine and clinical physician training. Some of the assistant residencies in urology, general surgery, internal medicine and radiology are available at the Gorgas Hospital, Canal Zone.

Officers who are not selected to enter residency training on January 1 or July 1, 1949, will, if qualified, be furnished a certificate indicating the date on which they will enter approved professional training. The program is designed to ensure that all qualified applicants will be given the opportunity of completing their requirements for certification by an American specialty board.

October 1, 1949, has been established as the deadline for receipt of applications from physicians who are interested in participating in this training program. Complete information and application blanks may be obtained from the Surgeon General, Department of the Army, Washington 25, D.C.

## Who Is This Man?

Now and then, in the pages of the  
*Clarion*, I run a biographical quiz,  
under the heading of "Who Is This  
Man?" For instance .

*"He was one of the earliest lovers  
in American history*

*"And yet he was too shy to court  
a woman outright .*

*"He came to the New World on  
the Mayflower .*

*"A cooper to repair the beer barrels  
accompanying the Pilgrims . . .*

*"Who is this man?"*

I thought that everybody was  
stumped But not Ma Hopkins, who  
returned the clipping to me with  
"John Alden" on it She recognized all  
the clues—including that reference to  
"beer" and "cooper"

*For Ma—who's read her history,  
knows that beer as the beverage of  
moderation, is as old in this land of  
ours as the never-ending American  
search for tolerance which brought the  
Pilgrims over to this country in the  
first place*

## CHRONIC SUBDURAL HEMATOMA\*

### Expansion of Compressed Cerebral Hemisphere and Relief of Hypotension by Spinal Injection of Physiologic Saline Solution

ALBERT A. LALONDE, M.D., J. AND W. JAMES GARDNER, M.D. ‡

CLEVELAND, OHIO

AFTER evacuation of a subdural hematoma the compressed hemisphere may fail to expand spontaneously. This may be a grave prognostic sign. Trotter,<sup>1</sup> Coleman,<sup>2</sup> Coblenz<sup>3</sup> and Voris<sup>4</sup> have discussed this aspect of subdural hematoma.

We agree with Coleman and Coblenz that failure of the compressed hemisphere to expand is more likely than cerebral edema to cause serious symptoms. Coleman found that the compressed hemisphere may not expand for several days after evacuation of the clot. It has been shown that the hemisphere may still be in a compressed state at autopsy even though the hematoma has been adequately evacuated.<sup>5</sup>

We have found that in some patients with postoperative recurrence of symptoms lumbar puncture may reveal the pressure to be subnormal. Re-exposure of the operative field in these cases demonstrates that the brain has failed to expand. The cerebrospinal-fluid hypotension and the associated state of compression of the hemisphere before and sometimes after evacuation of the hematoma may produce symptoms and signs indistinguishable from those of increased intracranial pressure.

Laudig, Browder and Watson<sup>6</sup> studied 143 cases of subdural hematoma and found that some patients with large hematomas had low cerebrospinal-fluid pressures, as measured in the lumbar thecal sac. This low intracranial pressure was substantiated at operation in some cases. The authors were unable to explain the altered state of consciousness in the presence of the low intracranial pressure.

Why the hemisphere fails to expand or why the intracranial pressure remains subnormal in these cases is not known, nor is it known which of these conditions is cause and which is effect. We have found that both conditions respond favorably to

the intraspinal injection of physiologic saline solution. The presence or absence of the hematoma membrane does not affect the syndrome, removal of the membrane is not necessary to cure it.

It may be significant that our patients were all in the sixth and seventh decades of life and did not have increased intracranial pressure before operation.

The literature contains reports of the treatment of this condition by intravenous injection of half-strength physiologic saline solution and placing the head in the dependent position<sup>7</sup>, instillation of distilled water into the cranial subdural space and intravenous injection of distilled water and saline solution, and removal of the inner membrane of the hematoma from the cortex.<sup>8</sup> It occurred to one of us (W. J. G.) that intraspinal injection of saline solution during the operation would quickly re-expand the compressed hemisphere and restore it to a more normal anatomic and physiologic state, as well as effecting a more complete removal of the hematoma by obliterating the cranial subdural space. This procedure has since been employed in all cases in which there is failure of spontaneous re-expansion of the compressed hemisphere.

The presence of the inner hematoma membrane has not prevented expansion of the compressed hemisphere in any case in which saline solution was injected intraspinally, and the expansion was accomplished in every case without raising the spinal-fluid pressure above the equivalent of 150 mm. of water. We believe that postoperative intracranial hypotension is less likely to occur after this procedure. No patient treated by such technic has developed evidence of cerebral edema after operation, and there has been prompt improvement of symptoms in all cases. In some cases we believe it to have been responsible for saving the patient's life.

With one exception the brain was under direct observation as it was being re-expanded by this procedure after evacuation of a subdural hematoma. In the majority of cases the brain was expanded

\*From the Cleveland Clinic and the Frank E. Bunts Educational Institute.  
Presented at a meeting of the Society of Neurological Surgeons, Omaha, Nebraska, June 11, 1948.

‡Formerly staff assistant, Department of Neurosurgery, Cleveland Clinic.  
Head, Department of Neurosurgery, Cleveland Clinic; professor of neurosurgery, Frank E. Bunts Educational Institute.

until it was in contact with the inner surface of the dura. Expansion was accomplished by intraspinal injection of saline solution in 5 cases and by intraventricular injection in 2 cases. The volume of fluid introduced at a single injection varied from 50 to 220 cc. No attempt was made to remove the inner hematoma membrane. Drainage was employed in only 1 of the 7 cases—drainage is not necessary if re-expansion of the hemisphere is complete.

In addition to the 7 cases of subdural hematoma in which the compressed hemisphere failed to expand spontaneously, this procedure was employed in 2 cases of intracranial hypotension following operation for other conditions.

### CASE REPORTS

**CASE 1** A 50-year-old man had bumped his head on a low porch about 1 month before admission on November 12, 1944. On the day of admission he had suddenly developed weakness of the left arm and leg and had difficulty in speaking. Roentgenograms of the skull showed the pineal gland displaced to the left. The spinal-fluid pressure was equivalent to 48 mm of water, and the fluid was xanthochromic.

On the night of November 14 the patient became comatose and developed Cheyne-Stokes respiration and extreme rigidity of the left arm and leg. The head was turned to the left and there was severe opisthotonos. A trephine opening was made on the right side just anterior to the fissure of Rolando, and a large, liquid, subdural hematoma was evacuated. The brain could be seen through the trephine opening and was depressed about 1.5 cm from the inner surface of the dura. This undoubtedly did not represent the point of greatest compression of the brain. The subdural cavity was irrigated with physiologic saline solution, and no solid clot was evident. The brain pulsed feebly and did not expand in the slightest. To expand the brain the patient was turned on his side, and a spinal puncture performed. When 220 cc of saline solution had been injected, the brain had expanded until it was almost in contact with the inner surface of the dura. A rubber tissue drain was then introduced into the subdural space, and the wound closed with a single layer of buried, interrupted silk sutures. On returning to his room the patient was quite restless. The respirations were 52 per minute, deep and labored. The temperature mounted rapidly to 103.4°F and the pulse was 160 per minute. In spite of these signs he was regaining consciousness and responded when spoken to. During the next 12 hours he drank 4000 cc of fluid but remained thirsty. Twelve hours after operation he was lucid, and the left hemiplegia was rapidly improving. The drain was then removed. The patient made an uneventful recovery and was discharged on the 12th postoperative day. He was not seen again until 3 years later, when he reported that he had had no symptoms referable to his head.

**CASE 2** A 59-year-old man had had severe frontal headaches, nausea and vomiting, as well as mild confusion, for 6 weeks. The headache was always relieved immediately when he lay down. On March 8, 1946 neurologic examination was negative. The spinal-fluid pressure was too low to be recorded. The fluid contained a protein of 58 mg per 100 cc and 10 cells. Pneumoencephalography was performed on March 25. The spinal-fluid pressure was equivalent to only 260 mm of water with patient in the sitting position. The total volume of fluid recovered was 99 cc, and encephalograms revealed evidence of an expanding lesion on the left side. A left frontal craniotomy disclosed a subdural hematoma. The hematoma was evacuated but the brain showed no tendency to re-expand. The wound was closed without drainage. Six hours later the patient was still comatose and had developed Cheyne-Stokes respiration and a bilateral Babinski reflex. The spinal-fluid pressure again was too low to record. A needle was introduced through the scalp into the cranial subdural space to permit evacuation of its contents. Fifty cubic centimeters of 1 per cent saline solution was then injected into the lumbar subarachnoid space, raising the spinal-

fluid pressure to the equivalent of 120 mm of water and producing a flow of bloody fluid from the scalp needle. Immediately thereafter, the patient opened his eyes, answered to his name, and moved his limbs for the first time since operation. The Babinski reflex could no longer be elicited on the left. On the day after operation the symptoms and signs recurred, and a similar procedure was carried out. 130 cc of saline solution being injected with the same immediate and gratifying response. The foot of the bed was elevated. On the 3rd postoperative day the symptoms again recurred, and the spinal fluid pressure was again not recordable. A continuous intraspinal drip of physiologic saline solution containing 30,000 units of penicillin per liter was started and maintained at a pressure equivalent to 120 mm of water. The patient improved during the first 24 hours of this therapy but during the next 24 hours he developed fever and stupor and the procedure was discontinued. His condition continued to grow worse until he appeared moribund. Recalling the experiments of Weed<sup>9</sup> in which intracranial pressure in animals was raised by the subarachnoid injection of India ink, and in the hope of demonstrating a point of leakage of the cerebrospinal fluid in case the patient came to autopsy, we decided to use this procedure. Accordingly, on the 10th postoperative day 0.5 cc of sterile India ink was injected into the lumbar spinal canal. The spinal-fluid pressure at that time was too low to record. Twelve hours later the patient's condition was improved, the spinal-fluid pressure was equivalent to 250 mm of water, and the fluid contained 137 polymorphonuclear leukocytes. A specimen of this fluid was sterile on culture. On the 11th postoperative day the patient was well oriented and able to get out of bed. However, on the 13th postoperative day he again developed severe headache, and the spinal-fluid pressure was once more too low to record. He was given hypotonic saline solution intravenously, but the hypotension persisted. By the 17th day, however, without further intraspinal injections, he was free of headache and was discharged. He made a complete recovery, and no sequelae were demonstrable when he was seen 8 months after operation.

This case demonstrated how rapidly the neurologic signs and symptoms due to cerebrospinal fluid hypotension will respond to the raising of intraspinal pressure. However, we do not recommend the subarachnoid injection of India ink to accomplish this purpose. We believe that the failure to obtain sustained improvement by the intraspinal injection of saline solution in this case was caused by an unsatisfactory evacuation of the cranial subdural space through the scalp needle. The effect would have been lasting if the operative wound had been reopened during the injection to make certain that the cavity was obliterated.

**CASE 3** A 68-year-old man was admitted to the Cleveland Clinic on June 29, 1946. On March 11 he had fallen from a desk on which he was standing and had struck the back of his head on the floor. He was unconscious for about 30 minutes. During the next 24 hours he was comfortable and alert, but then became restless, incoherent and finally stuporous. He was treated by lumbar punctures, with temporary improvement.

Neurologic examination revealed a right hemiparesis, right homonymous hemianopsia and aphasia. The spinal fluid pressure was equivalent to 180 mm of water, and the fluid was clear and colorless. Roentgenograms of the skull showed a linear fracture on the left side with the pineal gland dislocated to the right.

On July 3 a left parietal craniotomy was performed. The exposed portion of the dura with the attached outer dural hematoma membrane was excised, and a large, liquid, subdural hematoma was evacuated. The brain was depressed 2.5 cm below the inner surface of the dura and showed no tendency to expand spontaneously. A spinal puncture was performed, and 130 cc of saline solution injected. The brain expanded until it was in contact with the dura. The bone was then replaced, and the wound closed without drainage.

On the 1st postoperative day the patient was no longer aphasic but was somewhat drowsy. A Babinski reflex was present on the right, and there was a slight weakness of the right side of the face. On the 2nd postoperative day he developed jargon aphasia and a bilateral Babinski reflex, but no demonstrable hemianopsia. The spinal-fluid pressure was equivalent to 170 mm of water, and the fluid was bloody. No fluid could be aspirated through the trephine opening in the skull. On the 5th postoperative day he was no longer aphasic, and neurologic examination was negative. He was discharged on the 10th postoperative day in excellent condition and was in good health when last seen 2 months after operation.

**CASE 4** A 64-year-old man was thrown from a horse in June, 1946, and was unconscious for 25 minutes. Two months later he suddenly developed severe headache and a left hemiparesis. Neurologic examination on September 24 revealed a left hemiparesis with a Babinski reflex. There was no papilledema, and the spinal-fluid pressure was equivalent to 170 mm of water. This fluid was clear and colorless. A pneumoencephalogram was made on September 28. All the fluid was removed, measuring 104 cc. The films showed no ventricular filling. On September 30 a right temporal trephine opening was made, and a large, coffee-colored, liquid, subdural hematoma was evacuated. As the brain did not expand, the patient was turned on his side, and 100 cc. of physiologic saline solution was injected into the lumbar canal. The needle then became dislodged, and the injection was discontinued, although this quantity was not sufficient to bring the brain into contact with the dura. The wound was closed without drainage. The patient awakened promptly after returning to his room and exhibited improvement of the hemiparesis. On the 5th postoperative day there was no demonstrable weakness of the extremities, and he was discharged the next day. He remained well until 19 days after operation, when he had a left jacksonian convulsion. A similar attack occurred 3 days later, with loss of consciousness and paresis of the left arm. He was readmitted to the hospital on October 25, and an encephalogram was made the next day. All the fluid was removed, measuring 119 cc. The initial pressure was normal. There was again no air in the ventricles, but the callosal sulcus was tilted, indicating an expanding lesion on the right. On October 28 bilateral trephine openings were made in the frontal and parietal regions. Only a small amount of chocolate-colored fluid was present on the right side. About 20 cc. of thick, coffee-colored fluid was evacuated through the left parietal trephine opening, and about 60 cc. of clear yellow subdural fluid was evacuated through the left frontal trephine opening. The incisions were closed without drainage, since the brain expanded spontaneously. The weakness of the left arm improved gradually, and the patient was discharged on the 5th postoperative day. Follow-up examination on January 23, 1948, revealed a slight weakness of the left hand grasp. The remainder of the neurologic examination was normal. He stated that he had had no headaches and had been doing his usual farm work since hospital discharge.

It may be significant that in this case, in which reoperation was necessary, the intraspinal injection of physiologic saline solution was discontinued before the hemisphere was restored to its normal shape.

**CASE 5** A 60-year-old man had been well until November 14, 1946, when he fainted while walking down the street, striking his head on the sidewalk. He was unconscious for about 5 minutes. During the next 2 weeks he complained of headache and failing memory and weakness of the left arm and leg. During January 1947, he developed a definite change in personality, and his headaches became severe. On January 22 he developed aphasia and stupor. Neurologic examination on March 1 revealed amimia on the right, ataxic gait and a Babinski reflex on the left. There was marked loss of memory. The spinal-fluid pressure was equivalent to 160 mm of water, and the fluid was faintly xanthochromic.

On March 4 with the patient in the supine position, trephine openings were made in front of each parietal emi-

nence. There was no subdural hematoma on the right, but on the left side a large quantity of coffee-colored subdural fluid was evacuated. The brain showed no tendency to expand. To avoid turning the patient on his side for a spinal injection it was decided to inject the saline solution into the right lateral ventricle, and 67 cc. of solution was introduced. This expanded the left hemisphere until it was in contact with the inner surface of the dura. The wound was closed without drainage. The patient awakened soon after returning to his room, and no aphasia or Babinski reflex could be elicited. There was no recurrence of symptoms, and he was discharged on the 5th postoperative day. Follow-up examination on February 21, 1948, revealed no neurologic deficit.

Ventricular injection of physiologic saline solution in these cases is a more simple procedure than spinal injection if the patient is operated upon in the supine position, but it may aggravate an existing incisural hernia. On the other hand, intraspinal injection of saline solution may reduce an incisural hernia.

**CASE 6** A 52-year-old man was struck by an automobile on February 15, 1947. He was unconscious for a few minutes but had no other complaints until April 13, when he developed increasingly severe suboccipital and frontal headache. On April 11 his left arm and leg became weak, and he was confused. Neurologic examination 2 days later revealed a left hemiparesis. There was no papilledema. At pneumoencephalography the initial spinal-fluid pressure was normal and 74 cc. of fluid was recovered. The ventricles were markedly displaced toward the left. A right parietal trephine was performed, with evacuation of a large, liquid, coffee-colored, subdural hematoma. The brain was depressed 2.5 cm below the dura. A left parietal trephine revealed a small subdural clot. One hundred cubic centimeters of physiologic saline solution was injected into the lumbar canal, but this quantity was not sufficient to effect a complete re-expansion of the right hemisphere. The wound was closed without drainage. The patient awakened soon after returning to his room, and the hemiparesis was much improved. On the 2nd postoperative day nausea and vomiting developed. The spinal-fluid pressure was equivalent to 210 mm of water. This fluid contained 6 white cells per cubic millimeter and a protein of 41 mg per 100 cc.\* On the 5th postoperative day neurologic examination was negative, and he was discharged. Follow-up examination on May 20 revealed no neurologic deficit.

**CASE 7** A 66-year-old woman was first seen at the Cleveland Clinic on May 12, 1947, because of paralysis of the left arm and leg. Three weeks previously she had slipped and fallen to the sidewalk, striking her head. She had not lost consciousness. One week later she awakened with weakness of her left arm and leg, which gradually progressed to complete paralysis. Neurologic examination revealed a left homonymous hemianopsia, paralysis of left lateral gaze, dilatation of the left pupil, a central type of facial weakness on the left and paralysis of the left arm and leg. The spinal-fluid pressure was equivalent to 160 mm of water. The fluid was clear and faintly xanthochromic. The next day bilateral trephine openings were made in the temporal regions. There was no abnormality on the left, but on the right side a large liquid subdural hematoma was evacuated. The brain failed to re-expand spontaneously. A cannula was introduced into the left lateral ventricle and 135 cc of physiologic saline solution was injected. This caused the right hemisphere to expand until it was in contact with the dura. The wounds were closed without drainage. There was pro-

\*Bedford<sup>18</sup> has reported the appearance of polymorphonuclear leukocytes in the cerebrospinal fluid in 9 out of 15 dogs by the introduction of isotonic sodium chloride into the cisterna magna, while no leukocytes appeared after the injection of distilled water or Ringer's solution (Dale's formula). We have had a similar experience after the intraspinal injection of 1 per cent saline solution in the treatment of cerebrospinal fluid hypotension from various causes although this meningeal reaction occurred very seldom. We believed that this reaction was probably due to an impurity in the saline solution since it does not invariably occur and plan to investigate this problem further. No symptoms of meningitis occurred in any of the cases of subdural hematoma in this paper.

gressive improvement in the strength of the left arm and leg from the 1st postoperative day, and the patient was discharged on the 7th postoperative day. Examination 1 month after operation revealed no neurologic deficit. When last seen on February 18, 1948, she had no complaints, and neurologic examination was negative.

This procedure was employed in the following cases of intracranial hypotension after operations for conditions other than subdural hematoma.

A 42-year-old man had a right frontal craniotomy on May 12, 1947, with removal of a pituitary adenoma. He awakened the evening of his operation and was in good condition. On the 1st postoperative day headache developed. The spinal-fluid pressure was equivalent to 210 mm of water, and the fluid was bloody. On the 2nd postoperative day he had a generalized convulsion and became somnolent. He was taken to the operating room, and the wound was reopened. When the section of bone was removed an extradural clot about 3 cm in thickness was disclosed. This clot was removed, and the dura opened, disclosing no intradural clot. The brain was moderately compressed below the inner surface of the dura, which was loosely closed, and the bone disk was replaced. On the next day the patient was more alert but complained of severe headache. The spinal-fluid pressure was equivalent to 165 mm of water. Five cubic centimeters of bloody fluid was removed, and the spinal-fluid pressure was equivalent to 110 mm of water. This relieved his headache, but on re-elevation of the head of the bed, the headache recurred and was relieved immediately when his head was lowered. On the 4th postoperative day he exhibited somnolence and complained of severe headache. During the next 48 hours the stupor deepened, and a bilateral Babinski reflex appeared. On the 6th postoperative day, with the patient in coma, the wound was reopened. The brain was found to be depressed to the same extent as at the time of closure of the previous exploration. There was no clot. The dura was closed, and a cannula was introduced into the anterior horn of the right ventricle. Forty cubic centimeters of physiologic saline solution was injected with some expansion of the dura, but when the bone was replaced the dura was still found to be depressed 1.5 cm from the inner table. The patient was then turned on his side, and a spinal puncture performed. After 150 cc of physiologic saline solution had been injected into the spinal canal the dura was in contact with the inner table. The spinal-fluid pressure at this point was just measurable. The wound was then closed without drainage. The patient awakened 2 hours after returning to his room, and his condition steadily improved. Forty-eight hours later he was normally alert and had no headache. He was discharged in good condition 9 days after the last operation.

This case shows that failure of the compressed hemisphere to expand is not peculiar to the subdural hematoma but may occur in acute extradural hematoma as well. The restoration of the shape of the brain to normal in this case appeared to be a life-saving measure.

A 57-year-old man had a right parietal craniotomy on November 4, 1947, with removal of a parasagittal meningioma. On the 1st postoperative day there was marked paresis of the left arm but less paresis of the left leg than had been present before operation. He was alert and talking. On the 2nd postoperative day he developed auricular fibrillation. The spinal-fluid pressure was equivalent to 110 mm of water. He then developed paralysis of the left arm and leg and became somnolent. A roentgenogram of the skull at that time showed the pineal gland to be in the midline. Thrombosis of the sagittal sinus was suspected, and heparin and dicumarol were started. On the 4th postoperative day he was more alert, and there was some movement of the left arm. On the 5th postoperative day a mild clonic convulsion occurred in the left side of the face and left arm. The spinal-fluid pressure was equivalent to 45 mm of water. On the 6th postoperative day he was comatose and could not be aroused. The spinal-fluid pressure was equivalent to 35 mm of water. Eighty cubic centimeters of physiologic saline solution was injected into the lumbar canal. When the spinal-fluid pressure had reached the equivalent of 120 mm of water the pa-

tient awakened and began to talk, and when the figure had reached 200 he was quite lucid. This improvement was not maintained, however, and the next day the spinal fluid pressure was too low to be recorded. Twenty cubic centimeters of physiologic saline solution injected into the lumbar canal raised the spinal-fluid pressure to the equivalent of 150 mm of water, and he again awakened and talked quite intelligently. Twelve hours later he was again stuporous, and the spinal-fluid pressure could not be recorded. Sixty cubic centimeters of physiologic saline solution was injected into the lumbar canal, raising the spinal-fluid pressure to the equivalent of 120 mm of water, with the same immediate gratifying result. Anticoagulant therapy was discontinued on the 7th postoperative day. Two days later the stupor had recurred, the foot of the bed was elevated, and 1000 cc of 0.5 physiologic saline solution given intravenously. There was some improvement, but it was not maintained. On the 10th postoperative day a continuous drip of saline solution into the lumbar canal was started. This was regulated to maintain the spinal-fluid pressure at the equivalent of 150 mm of water, and he showed immediate improvement. Later he was again given 1000 cc of 0.5 physiologic saline solution intravenously. The intraspinal drip was continued for 15 hours, and a total of 650 cc introduced. He was much brighter than he had been on any day since operation. The left hemiplegia persisted. There was no recurrence of stupor and his general condition was excellent at the time of his discharge on the 15th postoperative day.

This patient again demonstrated how rapidly the neurologic signs and symptoms due to cerebrospinal fluid hypotension will respond to the raising of the intraspinal pressure.

#### SUMMARY

Failure of the compressed hemisphere to expand after evacuation of a subdural hematoma is associated with cerebrospinal-fluid hypotension and may be a grave prognostic sign.

The compressed hemisphere may be expanded mechanically at the time of operation by the injection of physiologic saline solution into the spinal subarachnoid space or into the lateral ventricle.

Expansion of the compressed hemisphere decreases or abolishes the subdural dead space, restores the brain to a more normal anatomic and physiologic state, and obviates the need for drainage of the subdural space.

No ill effects have occurred from this procedure. Improvement has been immediate and dramatic.

This series of cases indicates that failure of expansion of the compressed hemisphere is more common in elderly patients who do not have increased intracranial pressure before operation.

The signs of intracranial hypotension may simulate those of intracranial hypertension.

## STREPTOMYCIN IN THE TREATMENT OF BACTERIAL ENDOCARDITIS\*

## Report of Two Cases

NORMAN L. CRESSY, M.D.,† WILLIAM J. LAHEY, M.D.,‡ AND PAUL KUNKEL, M.D.§

NEW HAVEN, CONNECTICUT

**E**XPERIENCE with streptomycin in the treatment of bacterial endocarditis is as yet limited. Hunter<sup>1</sup> discussed 18 cases and suggested that streptomycin is the drug of choice in endocarditis caused by gram-negative bacilli and penicillin-resistant, gram-positive cocci, and in infections that fail to respond to maximal penicillin treatment.

The case reports that follow present features of bacteriologic and therapeutic interest. The causative organism in the first case was a gram-negative, anaerobic, non-spore forming bacillus (*bacteroides*), and in the second, a highly resistant alpha-hemolytic streptococcus.

**CASE 1** J. P., a 46-year-old man, entered the hospital in November, 1946, with a 2-month history of fever, night sweats, chills and intermittent pain along the inner aspect of the upper part of the left thigh. He had increasing weakness and fatigability and had lost 25 pounds. There was no history of antecedent trauma, infection or rheumatic fever.

Physical examination disclosed a pale and hyperpneic patient who appeared acutely ill. Herpes labialis was present, and the pharynx was moderately injected. The lungs were clear, and the heart was normal. There was spasm of the adductor muscles of the left thigh and marked tenderness at the attachment of these muscles at the pelvic level. There was no swelling, heat or redness, and no tenderness along the course of the venous channels.

The temperature was 103°F, the pulse 110, and the respiratory rate 25. The blood pressure was 115/75.

Examination of the blood revealed a red-cell count of 4,000,000, with a hemoglobin of 11.5 gm., and a white-cell count of 15,200, with 75 per cent neutrophils. The hematocrit was 36, and the corrected sedimentation rate was 108 mm. in 1 hour. The serologic test for syphilis was negative, and agglutinations for the organisms of typhoid and paratyphoid fever and for brucella and proteus OX19 were negative. A blood culture was sterile.

An electrocardiogram and an x-ray film of the chest were within normal limits. X-ray examinations revealed only slight roughening of the posterior, proximal, periosteal surfaces of both femurs but no definite evidence of osteomyelitis.

The patient continued to have a maximum temperature of 103°F. A diagnosis of osteomyelitis of the left femur was considered initially, and on the 7th hospital day exploratory aspiration was attempted. No pus was obtained. Despite the absence of a specific diagnosis penicillin was then instituted in dosage of 130,000 units intramuscularly every 3 hours. No improvement was noted, and the drug was discontinued on the 20th hospital day. On the 26th hospital day a flame-shaped hemorrhage was noted beneath the nail of the right index finger. Repeated blood cultures had shown no growth. On the 32nd hospital day the patient complained of double vision. Examination revealed the presence

of paralysis of the left superior rectus ocular muscle. The spinal fluid was normal. The diplopia persisted throughout the patient's hospital course.

On the 35th hospital day a Grade II apical systolic murmur was detected. On the same day a petechial lesion was noted on the left heel. Aspiration and culture yielded an anaerobic, gram-negative coccobacillus identified as *bacteroides*, species undetermined. On the 39th hospital day a blood culture incubated in thioglycollate medium yielded an organism similar to that isolated from the petechia. The organism at no time grew out in numbers sufficient for the determination of its sensitivity to penicillin and streptomycin. On the 43rd hospital day the spleen was palpable. On the following day a faint diastolic murmur was heard along the left sternal border.

On the 45th hospital day the blood culture was still positive, and streptomycin was instituted in a dosage of 1 gm. every 6 hours intramuscularly. Seventeen subsequent blood cultures were sterile. Despite the disappearance of bacteremia the temperature curve remained elevated, and on the 51st hospital day penicillin was again started in dosage of 10,000,000 units intravenously per day. Severe, generalized urticaria promptly appeared, and after 5 days penicillin was discontinued. On the 56th hospital day sulfadiazine in an initial dosage of 4 gm. and a subsequent dosage of 1 gm. every 4 hours was begun. On the 57th hospital day the patient complained of a "sticking" pain in the left upper quadrant, with radiation to the left shoulder. This was interpreted as an episode of splenic infarction.

The patient's clinical status continued essentially unchanged, and on the 62nd hospital day streptomycin was discontinued. In 2 days the patient was afebrile. On the 68th hospital day the temperature spiked to 102°F. Examination revealed signs of thrombophlebitis in the left leg. The patient was put on anticoagulant therapy with heparin and dicoumarol. Sulfadiazine was discontinued. Two days later bilateral femoral-vein ligation was performed. A large thrombus was removed from the left side but unfortunately was discarded before cultures could be taken. Two days postoperatively the temperature returned to normal. On the 74th hospital day there were symptoms and radiologic signs of pulmonary infarction, which promptly cleared.

The patient's course, thereafter, was essentially uneventful. The aortic diastolic murmur increased, however, and there was some widening of the pulse pressure. Tachycardia persisted for several weeks. The sedimentation rate slowly returned to normal. During the last hospital month the spleen was no longer palpable. Frequent electrocardiograms had been taken throughout the hospital course. Serial tracings from the 91st to the 116th hospital day showed changes in the ST segments and T waves suggestive of myocardial damage, although the patient was asymptomatic. The diplopia persisted and was not correctable by lenses. The patient was discharged on the 116th hospital day. Final x-ray films of the chest with a barium swallow showed no abnormalities in the configuration of the heart.

Three months later the patient was feeling well and had regained his former weight of 198 pounds. The blood pressure was 130/55. There was no change in the character of the aortic diastolic murmur. There was no anemia and the white-cell count and sedimentation rate were normal. An electrocardiogram and an x-ray film of the chest were within normal limits. Surgery directed toward the correction of the diplopia was successfully accomplished.

The pertinent features of the patient's hospital course are presented in Figure 1.

Reports of septicemias due to gram-negative, anaerobic, nonspore forming bacilli (*bacteroides*) are few, and reports of endocarditis are corre-

spondingly rare. The organisms are natural inhabitants of mucous membranes from which sites they may invade the tissues, blood or body cavities.<sup>2,3</sup> The most frequent severe bacteroides infections are septicemias arising from throat infection or following operation on the colon, and meningitides arising from chronic otitis media.<sup>4</sup> The genus is not well defined, and accurate identification is often unsatisfactory. Lewis and Rettger<sup>5</sup> state, "Differences in methods, inconsistent nomenclature, and inherent differences in the organisms

In the past these infections have usually been fatal, although a few patients have apparently recovered after administration of sulfonamides.<sup>10,11</sup> Foley,<sup>12</sup> in a recent study, found the genus bacteroides highly resistant to streptomycin *in vitro*, as well as to sulfadiazine and sulfathiazole. The role of streptomycin in this patient's recovery can only be inferred in view of the overlapping administration of penicillin and sulfadiazine. It is, however, noteworthy that the last positive blood culture was obtained on the day streptomycin was instituted

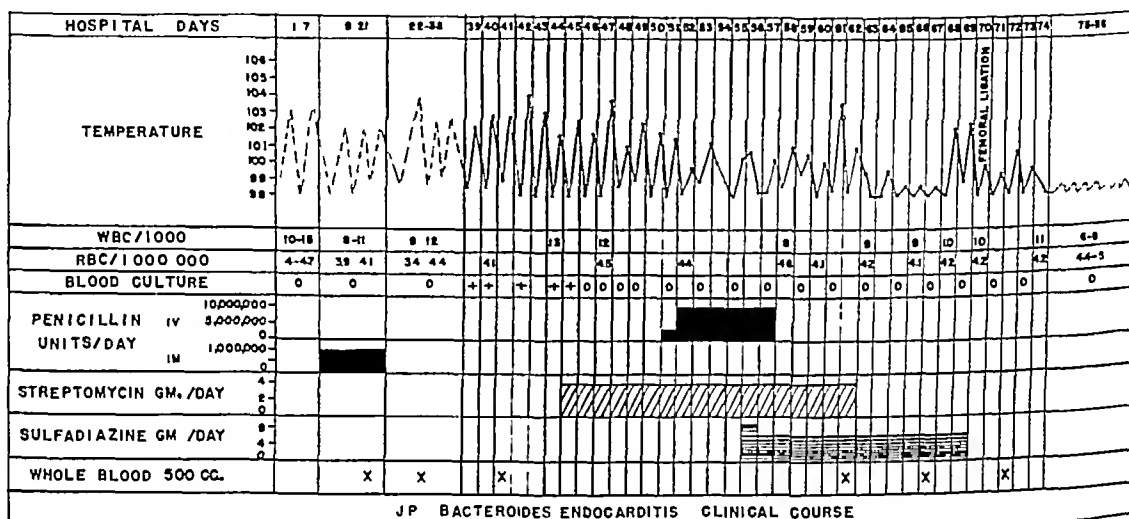

FIGURE 1 Clinical Course in Case 1

themselves have contributed to provide a complex and confusing picture." It is possible that the organism isolated from some cases of endocarditis and reported as an "unidentified gram-negative bacillus" would be classified as bacteroides by some laboratories. Smith and Ropes<sup>4</sup> believe that bacteroides infections are much more common than is appreciated clinically. The organisms are readily missed in routine bacteriologic study, since they are anaerobic, grow slowly and often require special medium. Bacteroides was first isolated from a petechia in this case and grew poorly and only in thioglycollate medium. This is of importance, since it has been shown that thioglycollate inhibits the bactericidal effect of streptomycin *in vitro*.<sup>6,7</sup> Hence, there are limitations to any sensitivity tests carried out in this medium.

In retrospect the presenting symptom of pain in the left upper thigh in this case is logically attributable to atypical thrombophlebitis. Reid et al.,<sup>8</sup> in analyzing 6 cases of septicemia due to bacteroides, found that thrombophlebitis was a constant feature. Appelbaum and Gelfand<sup>9</sup> report a case with an unidentified gram-negative bacillus, and it is significant that a prominent feature of the patient's presenting illness was thrombophlebitis.

Furthermore, negative cultures were obtained before the intravenous use of penicillin and sulfadiazine. It may be that the combination of drugs produced a therapeutic effect.

The prompt subsidence of fever after cessation of streptomycin suggests that the drug was exerting a toxic effect during the latter part of its administration. No vestibular, renal or dermatologic abnormalities were noted.

The serial electrocardiographic changes noted after the patient was clinically well are of interest. Seabury,<sup>13</sup> in an analysis of 165 cases of bacterial endocarditis, found that 25 per cent showed myocardial infarction at autopsy.

CASE 2. E. S., a 75-year-old man, was admitted to the urologic service of the hospital on February 16, 1947, with the chief complaint of trouble in passing urine. Two and a half weeks before entry he had been admitted to another hospital and placed on constant urinary drainage.

Physical examination revealed a well developed and fairly well nourished man in no acute distress. The chest was clear and there was a Grade II, blowing systolic murmur at the apex of the heart. The peripheral arteries were markedly sclerotic. The prostate was greatly enlarged and tender. An indwelling catheter was present.

The temperature was 99.8°F, the pulse 110, and the respiratory rate 22. The blood pressure was 170/70. Examination of the blood revealed a red-cell count of 4,150,000, with a hemoglobin of 13.5 gm, and a white cell

count of 15,650, with 85 per cent neutrophils. The specific gravity of the urine was 1.010, and there were 5 to 6 white blood cells per high-power field in the sediment. The blood urea nitrogen was 20 mg per 100 cc., and the total blood protein was normal. An x-ray film of the chest, an electrocardiogram and an intravenous pyelogram were within normal limits.

Sulfadiazine, in a dosage of 0.5 gm., was given four times daily. Cystoscopy was performed on the 6th hospital day. Culture of the urine yielded an alpha-hemolytic streptococcus and *Pseudomonas aeruginosa*. On the 9th hospital day the

mycin therapy. This organism grew in 500 but was inhibited by 50 units of streptomycin per cubic centimeter. On this day the patient's condition abruptly deteriorated, and he presented the picture of collapse, with a marked fall in blood pressure and clouding of consciousness. Since the bacteremia had returned and since it was not known what role streptomycin might be playing in the patient's sudden failure, the drug was discontinued.

Terminally, bronchopneumonia and oliguria developed. The blood urea nitrogen rose to a height of 37 mg per 100 cc., and the urinary sediment showed hyaline and granular

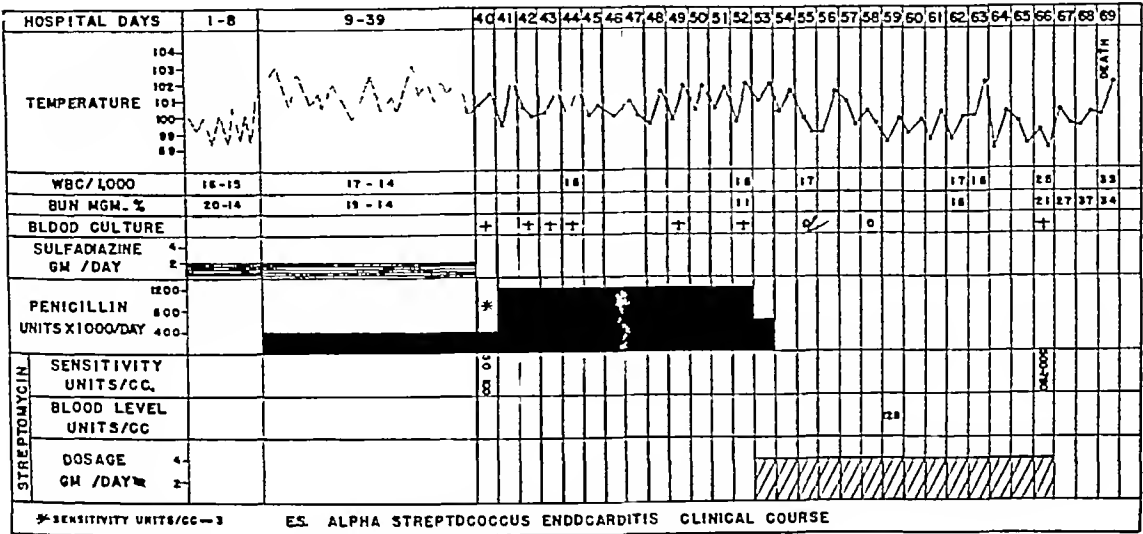

FIGURE 2 Clinical Course in Case 2

temperature rose to 103°F, and penicillin was started in a dosage of 50,000 units intramuscularly every 3 hours. On the 10th hospital day a suprapubic cystostomy and bilateral vasectomy were performed. Pathological examination of the specimen showed chronic inflammation. On the 5th postoperative day there was evidence of epididymitis. This subsided during the next hospital week, but the patient continued to run a temperature ranging from 100 to 102°F. Urine cultures were persistently positive.

The course continued essentially the same until the 40th hospital day, when, despite the continued administration of 400,000 units of penicillin daily, culture of the blood yielded an alpha-hemolytic streptococcus. On the same day a diastolic murmur was detected along the left sternal border. The spleen was not palpable, there were no petechiae and there was no anemia. Penicillin dosage was increased to 1,200,000 units daily. Subsequent sensitivity tests determined that the organism isolated from the blood grew in 2 but was inhibited by 3 units of penicillin per cubic centimeter. The blood cultures continued positive. Sensitivity tests to streptomycin indicated that the organism grew in 50 but was inhibited by 100 units of streptomycin per cubic centimeter. In view of the lack of response to the increased dosage of penicillin, it was discontinued on the 52nd hospital day, and treatment with streptomycin was instituted, 0.5 gm being given every 3 hours intramuscularly. The urine was alkalized.

Initially there was evidence of a favorable response. Blood cultures taken on the 2nd and 5th days of streptomycin therapy were negative. The temperature declined from a high of 102°F on the day streptomycin was started to near normal on the 7th day. On that day the blood streptomycin level was 128 units per cubic centimeter.

On the 11th day of streptomycin therapy the temperature again rose to 102°F. Culture of the blood again yielded an alpha-hemolytic streptococcus on the 14th day of strepto-

casts. Death occurred on the 69th hospital day. The clinical data are summarized in Figure 2.

Autopsy revealed bacterial endocarditis superimposed on calcareous aortic stenosis. Culture of the vegetations yielded an alpha-hemolytic streptococcus. The kidneys showed only mild arteriosclerotic changes.

This case emphasizes several important considerations in the management of bacterial infections. Penicillin is considered to be the drug of choice in the management of infections with a gram-positive coccus. In this case however, the presence of an alpha-hemolytic streptococcus in the blood was first demonstrated while the patient was receiving penicillin in an amount ordinarily sufficient for the control of this organism. Its relatively low sensitivity to penicillin—3 units per cubic centimeter—was subsequently confirmed. (In 12 cases of bacterial endocarditis, Goerner, Geiger and Blake<sup>14</sup> found the sensitivity of the alpha-hemolytic streptococcus to be in the range of 0.02 to 0.05 units per cubic centimeter.) Further studies in this case revealed that the resistance of the organism to streptomycin was also relatively high. Despite this the drug was given empirically. The temporary disappearance of bacteremia and the general clinical improvement early in the course of streptomycin therapy seem to justify this course

The ultimate failure of therapy was largely caused by the rapid, tenfold increase in the resistance of the organism to streptomycin.

In such resistant infections, in which studies in vitro show relative resistance of the organism to both streptomycin and penicillin, the use of both drugs together might be effective as suggested by Hunter.<sup>1</sup> Laboratory controls in the management of such cases are important.

The blood streptomycin level of 128 units per cubic centimeter observed in this case was unusually high and may have been related to decreased excretion. It perhaps explains the initial response of the patient to therapy. Such levels might be accompanied by a higher incidence of toxic effects. Hirshfeld,<sup>16</sup> however, has reported a level of 171 units per cubic centimeter in 1 case without toxic manifestations. An unusual type of fatty infiltration in the livers and kidneys of animals given large doses of streptomycin has been described by several investigators.<sup>16</sup> Similar changes have been reported in man in at least 1 case.<sup>17</sup> Fat stains of tissue sections in the fatal case reported above revealed no evidence of kidney or liver damage attributable to streptomycin.

#### SUMMARY

Two cases of bacterial endocarditis in which streptomycin was employed are presented, and certain important features are discussed.

In a case in which the patient recovered, the organism was an anaerobic, gram-negative, non-spore-forming bacillus (bacteroides).

In a fatal case, the etiologic agent was an alpha hemolytic streptococcus, which was highly resistant to both penicillin and streptomycin.

## CARCINOMA OF THE RECTUM

FREDERICK S HOPKINS, M D,\* AND ROBERT C TATE, M D†

SPRINGFIELD, MASSACHUSETTS

THIS report is based on the cases of carcinoma of the rectum that have been seen in the Cancer Section of the Westfield State Sanatorium since it opened in the fall of 1937. Of the 165 patients seen before 1943 and so available for a five-year study 112 had surgical treatment at Westfield. The latter group constitutes the principal basis for this statistical study.

The incidence was much greater in the male sex, there being 81 men and 31 women.

The average age was sixty-seven years, the sixth and seventh decades furnishing most of the cases, although both the third and ninth decades were represented, with 2 cases each.

The principal symptoms in order of frequency were blood in the stool, change in bowel habit, diarrhea, constipation, tenesmus and pain.

The duration of symptoms was less than three months in only 28 cases whereas in 7 it was over two years.

An extremely important feature of the physical examination is requesting the patient to strain while the physician is doing a digital rectal examination. With this procedure the tumor was felt in 92 cases or 82 per cent. The lesion was within 10 cm. of the anus in 90 cases.

Sigmoidoscopy with biopsy of the lesion was done routinely. Cystoscopy was done in most of the cases and revealed bladder invasion in 6. Barium enemas were usually done to assist in the identification of multiple lesions. Routine chest films revealed 3 cases of unsuspected lung metastases. About a third of the patients had a significant anemia, and slightly less had sufficient hypoproteinemia to require special preoperative preparation.

There were 5 patients who had clinical evidence of inguinal-lymph-node metastases. These were all cases of adenocarcinoma starting in the rectum but involving the anal canal. Only 2 of these had biopsies of the inguinal lymph nodes, and these showed metastatic carcinoma.

In 15 cases or 13 per cent, there was another primary cancer. Five of these involved the colon.

The study and preparation of the patient for operation required approximately a week. During the period covered by this survey cathartics and enemas were used routinely. Since then these have been replaced by sulfasuxadine usually given in the dose of 2 gm. every four hours for five days.

One hundred and twelve patients had operations done by 18 members of the visiting and resident staff. In only 50 of these cases was there any possibility of cure, the others having definite evidence of incurability such as metastases to the liver. Of the latter group 46 were simple colostomies, and 15 were palliative resections. The one-stage abdominoperineal resection of Miles is now done in nearly all cases. We still believe that there is occasionally an indication for the Lockhart-Mummery procedure in the patient with a tumor low in the rectum who is a very poor risk. This consists in a sigmoid-loop colostomy followed within two weeks by a posterior resection of the rectum and lower sigmoid.

All patients undergoing abdominoperineal resections received transfusions during operation. The average number of transfusions in such cases was two and a half.

In most of the Miles operations the end of the sigmoid was brought out through the left rectus incision as the permanent colostomy, and the lateral gutter was closed. During this period catgut sutures were usually used. There were 17 cases of hernia around the stoma, though none of these were incapacitating. With the use of a transverse incision and cotton sutures we have had no hernias.

The average time in the hospital after operation was thirty-five days. Since 1942 it has been twenty-eight days, and many patients go home in three weeks.

The time required for the healing of the posterior wound varied greatly. Five were healed in one month, and yet 15 required over three months.

Urinary-tract complications were frequent. All patients were placed on constant bladder drainage through a urethral catheter. The average time until the patient could void with negligible residual urine was nineteen days. Five patients had some permanent difficulty in urinary control.

The five-year results are as follows. Of the 35 patients who had the Miles operation with hope of cure 7 were postoperative fatalities, 13 are well, 9 died without any evidence of recurrence, 2 died with possible recurrence though there was no evidence of it on recent examination, 2 are living with recurrence, and 2 died with definite recurrence. One patient with a two-stage resection by the Daniel F. Jones technic, 1 with a Hochenegg sphincter-saving operation and 1 with a local removal of a malignant polyp are alive and well after five years. Nine Lockhart-Mummery operations were done in cases in which the liver was not involved. One

Springfield Hospital.

†Formerly assistant superintendent, Westfield State Sanatorium.

The ultimate failure of therapy was largely caused by the rapid, tenfold increase in the resistance of the organism to streptomycin.

In such resistant infections, in which studies in vitro show relative resistance of the organism to both streptomycin and penicillin, the use of both drugs together might be effective as suggested by Hunter.<sup>1</sup> Laboratory controls in the management of such cases are important.

The blood streptomycin level of 128 units per cubic centimeter observed in this case was unusually high and may have been related to decreased excretion. It perhaps explains the initial response of the patient to therapy. Such levels might be accompanied by a higher incidence of toxic effects. Hirshfeld,<sup>15</sup> however, has reported a level of 171 units per cubic centimeter in 1 case without toxic manifestations. An unusual type of fatty infiltration in the livers and kidneys of animals given large doses of streptomycin has been described by several investigators.<sup>16</sup> Similar changes have been reported in man in at least 1 case.<sup>17</sup> Fat stains of tissue sections in the fatal case reported above revealed no evidence of kidney or liver damage attributable to streptomycin.

#### SUMMARY

Two cases of bacterial endocarditis in which streptomycin was employed are presented, and certain important features are discussed.

In a case in which the patient recovered, the organism was an anaerobic, gram-negative, non-spore forming bacillus (bacteroides).

In a fatal case, the etiologic agent was an alpha hemolytic streptococcus, which was highly resistant to both penicillin and streptomycin.

## MEDICAL PROGRESS

### VIRAL HEPATITIS\*

SYDNEY S. GELLIS, M.D.,† AND CHARLES A. JANEWAY, M.D.‡

BOSTON

**R**ECENT articles concerning infections of the liver by viral agents<sup>1,2</sup> have reviewed with great detail present-day concepts of such infections. The purpose of the present report is to summarize briefly the studies published during 1947 and the early part of 1948 on infectious hepatitis and homologous serum hepatitis.

Owing to the fact that no laboratory animals have been found to be susceptible to hepatitis virus, human volunteers still form the only source of experimental tests designed to furnish additional information regarding the etiologic agent or agents. As a result, modern knowledge of the virus of hepatitis is based on extremely limited studies, some of which have served to cloud rather than elucidate controversial issues concerning the nature, mode of spread, contagiousness, incubation period, immunologic relations and control of the viral agent. Perhaps the most controversial problem is the relation between the agent of infectious hepatitis and homologous serum jaundice.<sup>3</sup> Despite experimental work carried out during the past few years, which appears to establish the agents as separate though closely related entities, workers in this field continue to endeavor to prove that the agents are one and the same, differing in their behavior by virtue of different modes of entry into the body. It seems reasonable to expect that the clarification of this particular problem can come not from field studies or theoretical considerations but from further experimental work with volunteers. Despite the similarities of the two types of viral hepatitis, infectious hepatitis and homologous serum hepatitis are considered separately for purposes of review.

#### INFECTIOUS HEPATITIS

##### *Clinical Studies*

Relatively little regarding clinical findings has been added to the literature on hepatitis during the past year. Several articles have appeared reviewing the clinical course of the disease.<sup>4-6</sup> Goodman<sup>7</sup> points out the need of recognizing that infectious hepatitis is a generalized disease, with liver involvement as the most striking manifestation. In his series splenomegaly occurred in 48 per

cent of the patients, although lymphadenopathy, which has been stressed by Barker,<sup>5</sup> was not present. In Goodman's series, the white-cell count varied from 2450 to 9000, with a normal differential count in the initial stages and a subsequent absolute increase in lymphocytes and mononuclear cells, which frequently showed vacuolization. He concludes that infectious hepatitis is a disease of the reticuloendothelial system, and that the liver changes that were so striking in soldiers of World War II were exaggerated owing to the poor state of nutrition of the men at the time of their infection.

Kunkel and Hoagland<sup>8</sup> have added to the clinical findings of infectious hepatitis the occurrence of spider angiomas in patients with this disease—a finding that, though previously observed, had been little emphasized. They found that approximately 30 per cent of the patients developed spider angiomas during the acute stage of the disease and that the incidence was much higher among patients with chronic hepatitis. The authors believe that the angiomas serve as a useful physical sign for following the transition from acute to chronic infectious hepatitis. Furthermore, their appearance in patients who have never developed frank jaundice may be of considerable help in the diagnosis of infectious hepatitis. It is also of interest that angiomas persist for a long time after a short, apparently mild attack of hepatitis.

Headache, which frequently occurs in patients early in the course of infectious hepatitis, was reported by Zimmerman et al.<sup>9</sup> to be present in 70 per cent of their cases, and the authors comment on the localization of the pain, which in most of the patients was orbital or frontal. In their series, itching of the skin occurred in 20 per cent of the patients, an unusually high figure in hepatitis.

Röntgenographic and gastroscopic studies of the stomach and duodenum of human volunteers with experimentally induced infectious hepatitis<sup>10</sup> have confirmed earlier reports of the presence of gastritis and duodenitis in infectious hepatitis. Inflammation of the gastrointestinal tract apparently occurs early in the disease and may last into convalescence.

##### *Infectious Hepatitis in Children*

Although this disease has always been considered to be milder in children than in adults, relatively few studies employing modern laboratory methods

\*From the Children's Hospital and the Department of Pediatrics, Harvard Medical School.

†Associate in Pediatrics, Harvard Medical School; chief Medical Out-patient Department, Children's Hospital.

‡Professor of Pediatrics, Harvard Medical School; physician-in-chief, Children's Hospital.

of these patients is living with recurrence, 1 died with cancer, and 2 died with questionable recurrence of cancer. The other 5 died without evidence of recurrence. All the patients on whom palliative operations were done are dead.

These results are not so good as many that have recently been reported. The high operative mortality of the earlier years can be attributed to lack of experience. The use of chemotherapy and a better understanding of fluid balance have also assisted in improving the results. In the past six years the mortality for the radical resections without liver metastases has been 6.6 per cent, and in three of the years there were no postoperative deaths in this group.

In the 10 cases without obvious liver metastases in which there were recurrences or suspected recur-

peritoneal reflection. The patients with extraperitoneal rectal carcinomas had a 74.4 per cent five year survival without lymph-node metastases, whereas those with involved nodes showed 37.5 per cent alive after five years. The corresponding figures for the intraperitoneal rectal and sigmoid lesions were 90 per cent and 51.4 per cent.

Twenty patients had x-ray treatment after a colostomy. Twelve of these are considered to have obtained definite relief and improvement. One survived over four years, and 1 over five years after the onset of symptoms.

SUMMARY AND CONCLUSIONS

The 112 cases of cancer of the rectum receiving surgical treatment at the Westfield State Sanatorium more than five years ago have been reviewed.

TABLE 1 Patients Surviving Operation without Known Liver Metastases

TYPE OF OPERATION	LYMPH NODE INVOLVEMENT	NO. OF CASES	FIVE YEAR CURES	FIVE-YEAR SURVIVALS WITH NO RECURRENCE	DEATH IN FIVE YEARS WITH NO RECURRENCE	DEATH WITH RECURRENCE	DEATH, RECURRENCE DOUBTFUL
Miles	No	25	13	1	7	1	1
Miles	Yes	5	1	0	2	1	1
Hochenegg sphincter saving resection	No	1	1	0	0	0	0
Jones	No	1	1	0	0	0	0
Lockhart-Mummery	No	7	0	1	4	1	0
Lockhart-Mummery	Yes	2	0	0	1	1	0
Lynch posterior resection	Yes	1	0	0	0	0	1

rences, 8 patients had local extension beyond the bowel, and 2 had vascular invasion in addition to an anaplastic type of lesion microscopically.

The results according to metastases in the regional nodes are shown in Table 1. Of the 32 patients without positive evidence of lymph node involvement 15 are well over five years later. Eliminating the 11 patients who died without any evidence of cancer gives 71.4 per cent apparent cures. For the Miles procedure alone our figure is 81.2 per cent. Of the 8 patients with involved lymph nodes only 1 was apparently cured. Eliminating the 3 patients who died without recurrence gives a 20 per cent five-year cure. These figures are somewhat similar to most of those recently reported. Colcock<sup>1</sup> reports from the Lahey Clinic 60 per cent five-year survivals in which the lymph nodes were not involved and 30.2 per cent in which they showed metastases. Rankin's<sup>2</sup> comparable figures are 43.8 per cent without lymph-node involvement and 27.3 per cent with metastases. In a very thorough study of involved lymph nodes Gilchrist and David<sup>3</sup> found their results better when the lesion was above the

It is realized that this series is small and that many of the rates are based on too few cases to be statistically significant. The operative mortality has steadily decreased with increasing experience, the most rapid drop occurring in 1942 with the introduction of chemotherapy and a better understanding of body chemistry. The Miles abdominoperineal operation is the procedure of choice for most cancers of the rectum. It apparently cured 81.2 per cent of our patients without obvious metastases who did not die of other causes. Those who survive lead normal lives and are not significantly hampered by a colostomy. Many more patients could be placed in this relatively fortunate group if every physician would make an adequate rectal examination whenever a patient reports a change in bowel habits or rectal bleeding.

## MEDICAL PROGRESS

## VIRAL HEPATITIS\*

SYDNEY S GELLIS, M D,<sup>†</sup> AND CHARLES A JANEWAY, M D<sup>‡</sup>

BOSTON

RECENT articles concerning infections of the liver by viral agents<sup>1,2</sup> have reviewed with great detail present-day concepts of such infections. The purpose of the present report is to summarize briefly the studies published during 1947 and the early part of 1948 on infectious hepatitis and homologous serum hepatitis.

Owing to the fact that no laboratory animals have been found to be susceptible to hepatitis virus, human volunteers still form the only source of experimental tests designed to furnish additional information regarding the etiologic agent or agents. As a result, modern knowledge of the virus of hepatitis is based on extremely limited studies, some of which have served to cloud rather than elucidate controversial issues concerning the nature, mode of spread, contagiousness, incubation period, immunologic relations and control of the viral agent. Perhaps the most controversial problem is the relation between the agent of infectious hepatitis and homologous serum jaundice.<sup>3</sup> Despite experimental work carried out during the past few years, which appears to establish the agents as separate though closely related entities, workers in this field continue to endeavor to prove that the agents are one and the same, differing in their behavior by virtue of different modes of entry into the body. It seems reasonable to expect that the clarification of this particular problem can come not from field studies or theoretical considerations but from further experimental work with volunteers. Despite the similarities of the two types of viral hepatitis, infectious hepatitis and homologous serum hepatitis are considered separately for purposes of review.

## INFECTIOUS HEPATITIS

*Clinical Studies*

Relatively little regarding clinical findings has been added to the literature on hepatitis during the past year. Several articles have appeared reviewing the clinical course of the disease.<sup>4-6</sup> Goodman<sup>7</sup> points out the need of recognizing that infectious hepatitis is a generalized disease, with liver involvement as the most striking manifestation. In his series splenomegaly occurred in 48 per

cent of the patients, although lymphadenopathy, which has been stressed by Barker,<sup>5</sup> was not present. In Goodman's series, the white-cell count varied from 2450 to 9000, with a normal differential count in the initial stages and a subsequent absolute increase in lymphocytes and mononuclear cells, which frequently showed vacuolization. He concludes that infectious hepatitis is a disease of the reticuloendothelial system, and that the liver changes that were so striking in soldiers of World War II were exaggerated owing to the poor state of nutrition of the men at the time of their infection.

Kunkel and Hoagland<sup>8</sup> have added to the clinical findings of infectious hepatitis the occurrence of spider angiomas in patients with this disease — a finding that, though previously observed, had been little emphasized. They found that approximately 30 per cent of the patients developed spider angiomas during the acute stage of the disease and that the incidence was much higher among patients with chronic hepatitis. The authors believe that the angiomas serve as a useful physical sign for following the transition from acute to chronic infectious hepatitis. Furthermore, their appearance in patients who have never developed frank jaundice may be of considerable help in the diagnosis of infectious hepatitis. It is also of interest that angiomas persist for a long time after a short, apparently mild attack of hepatitis.

Headache, which frequently occurs in patients early in the course of infectious hepatitis, was reported by Zimmerman et al.<sup>9</sup> to be present in 70 per cent of their cases, and the authors comment on the localization of the pain, which in most of the patients was orbital or frontal. In their series, itching of the skin occurred in 20 per cent of the patients, an unusually high figure in hepatitis.

Roentgenographic and gastroscopic studies of the stomach and duodenum of human volunteers with experimentally induced infectious hepatitis<sup>10</sup> have confirmed earlier reports of the presence of gastritis and duodenitis in infectious hepatitis. Inflammation of the gastrointestinal tract apparently occurs early in the disease and may last into convalescence.

*Infectious Hepatitis in Children*

Although this disease has always been considered to be milder in children than in adults, relatively few studies employing modern laboratory methods

\*From the Children's Hospital and the Department of Pediatrics, Harvard Medical School.

<sup>†</sup>Associate in Pediatrics, Harvard Medical School; chief, Medical Outpatient Department, Children's Hospital.

<sup>‡</sup>Professor of Pediatrics, Harvard Medical School; physician-in-chief, Children's Hospital.

in children have appeared in the literature. In the two institutional outbreaks reported by Horstmann and his co-workers,<sup>11</sup> studies comparable to those made in Army and civilian outbreaks involving adults reveal that the disease in children is indeed a mild one: the icteric stage averaged 98 days, whereas in military personnel the average period of icterus was 27 days, and no patient revealed evidence of protracted convalescence or prolonged jaundice. The authors point out that differences in epidemics can be due to variations in virus strains, however, inasmuch as previous observations are similar to those of the present study, it appears reasonable to conclude that the disease is milder in children. Randolph and DeVito,<sup>12</sup> in a review of 32 children with infectious hepatitis seen at the Children's Hospital, Washington, D. C., found that all but 3 had fever with their infection and that the highest temperature occurred during the first two days of the preicteric stage, which averaged 7 days. In their series there were three times as many female as male patients. Webb et al.<sup>13</sup> have observed in children with acute infectious hepatitis a higher incidence of hepatitis without jaundice than with jaundice. The great difference in incidence of hepatitis without jaundice in various outbreaks reported is interesting; it suggests either variations in the strains of virus or different criteria for the diagnosis of the syndrome. Furthermore, the similarities between infectious hepatitis with or without jaundice and infectious mononucleosis suggest that other diseases give rise to the clinical picture of viral hepatitis. For this reason the diagnosis of infectious hepatitis should be made by exclusion.<sup>14</sup> Abrams<sup>15</sup> has reported a patient with infectious mononucleosis whose jaundice persisted for eleven weeks. This author emphasizes the need of repeated heterophil-antibody tests in patients with apparent infectious hepatitis before the diagnosis of infectious mononucleosis is excluded. Sufficient testing for heterophil antibodies appears to have been performed to date so that the test when positive may be used to distinguish between infectious hepatitis and infectious mononucleosis. McNicholl<sup>16</sup> has reported 2 patients with hepatitis possibly related to mumps. One developed jaundice and liver enlargement within a week of the onset of mumps while the parotid swelling was still present. The second patient was an adult whose jaundice and liver enlargement occurred five weeks after the onset of the parotitis. Although it is possible that the liver involvement in these patients was due to infectious hepatitis, numerous infections may give rise to inflammation of the liver with a clinical picture similar to that of acute infectious hepatitis.

### *Chronic Infectious Hepatitis*

At present the relatively new concept of a chronic stage of infectious hepatitis has been widely accepted. There can be no valid argument against

this concept when applied to patients who, recovering from their acute illness, continue to have large, tender livers, anorexia, nausea, right-upper-quadrant pain and laboratory tests indicative of persistent liver disturbance. However, the diagnosis of chronic hepatitis in patients clinically recovered from their disease, but whose laboratory tests continue positive, is still a matter of controversy and will continue so until improved tests or greater understanding of present-day tests have been achieved. The diagnosis on the basis of the persistence of a single type of positive test is open to question, but the minimal amount of liver dysfunction, as measured by modern laboratory tests, required to warrant the diagnosis has not yet been established. There is still no single test to determine liver dysfunction in infectious hepatitis comparable to the sedimentation rate in the determination of persistent rheumatic activity. Thus, until chronic hepatitis is more clearly defined, the reported incidence of this stage of the disease will vary considerably.

Klatskin and Rappaport,<sup>17</sup> in a study of 217 patients considered fully recovered from acute infectious hepatitis, found that half had residua consisting of fat intolerance, liver pains, hepatomegaly or impaired liver function for periods ranging up to twenty-seven years. The only factor they could correlate with the occurrence of residua was the intensity of jaundice during the acute attack; they found no relation between lack of bed rest and persistence of symptoms and signs. Since no liver biopsies were done on these patients, the authors were unable to relate the findings to structural changes. Kunkel, Labby and Hoagland<sup>18</sup> studied 350 men with acute infectious hepatitis and found that 60 (17 per cent) showed an abnormal convalescence, of these, 47 suffered a simple relapse with recovery, 2 a relapse with transition to chronic hepatitis, 4 chronic hepatitis and 7 persistent hyperbilirubinemia. Eight patients (23 per cent) did not recover completely after more than a year. The authors point out that these were older men and suggest that more conservative care is needed for patients over thirty years of age than for those in the younger age groups.

The relation between chronic hepatitis and cirrhosis of the liver continues to be a highly controversial one.<sup>19</sup> On theoretical grounds alone, infectious hepatitis appears to be a likely explanation for many cases of cirrhosis of the liver, in view of the fact that it may occur without visible jaundice and therefore not be diagnosed. Klatskin and Rappaport<sup>17</sup> found no symptoms of portal cirrhosis in their series but state that nodular cirrhosis may follow infectious hepatitis. Howard and Watson<sup>20</sup> have collected 6 cases of cholangiolitic (Hanot) cirrhosis and 15 of portal (Laennec) cirrhosis in which there was an antecedent history indicative of infectious hepatitis. These authors believe that in a certain small per-

centage of cases hepatitis becomes chronic or recurrent and may ultimately lead to cirrhosis. On the other hand, when patients with cirrhosis are studied, it is their opinion that antecedent hepatitis plays a significant etiologic role. Flood and James<sup>21</sup> studied 37 patients with viral hepatitis persisting for over two months after the onset of symptoms. Biopsies were performed on 15, in 12 of whom the biopsy showed evidence of periportal inflammation at intervals varying from two to twenty-five months after onset. The authors concluded from their series that there was little to suggest cirrhosis, and that complete recovery is to be expected after prolonged hepatitis. However, 1 patient in the series with homologous serum hepatitis, whose symptoms never completely disappeared, and whose death occurred three years after the onset of symptoms, revealed marked cirrhosis of the liver at post-mortem examination. It is stated that this case, which "may have been a sequel of acute hepatitis, should be interpreted with caution because of the rarity of frank cirrhosis following acute hepatitis." If this case is included, one might also draw the conclusion that cirrhosis after acute hepatitis is not such a rare condition. Fearnley<sup>22</sup> reported a patient who developed clinical signs of portal cirrhosis of the liver with ascites four years after an attack of infectious hepatitis. At post-mortem examination, however, the liver showed subacute necrosis with a multiple nodular hyperplasia. Spellberg<sup>23</sup> described 2 cases of portal cirrhosis following acute hepatitis, probably of the homologous serum type. Sherlock<sup>24</sup> reported 9 patients with cirrhosis developing after infectious hepatitis and concluded that infectious hepatitis appears to be an important etiologic factor in classic portal cirrhosis.

Kelsall, Stewart and Witts,<sup>25</sup> in reviewing their cases of subacute and chronic hepatitis, came to the conclusion that in hepatitis as in nephritis every gradation of chronicity exists and that various types of cirrhosis may develop in the course of the hepatitis, whether it is due to a virus, a chemical poison or an unknown etiologic agent. They reported that in the Oxford area cirrhosis is considerably more common in women than in men and that alcohol no longer ranks as an important etiologic factor. In his follow-up examination of 400 Navy men with acute infectious hepatitis who had been studied from the onset of the disease Kunkel<sup>1</sup> found none who had developed ascites or other evidence of severe cirrhosis. However, he studied 5 other young service men<sup>26</sup> in whom liver biopsy or post-mortem examination revealed large masses of regenerated liver cells without a lobular pattern, surrounded by dense areas of fibrous tissue. He believed that the picture was different from that in the usual portal cirrhosis and appeared similar to the post-necrotic type of cirrhosis described by Mallory. As further evidence of the difference between post-hepatic cirrhosis and portal cirrhosis

Kunkel states that the former is rarely amenable to the usual dietary forms of treatment that are valuable in portal cirrhosis. In another series of 82 patients with acute infectious hepatitis, studied in Army hospitals<sup>27</sup> 4 were considered to have gone on to early cirrhosis. This diagnosis was not confirmed by biopsy. McHardy et al.<sup>28</sup> reported the cases of 16 patients with initially severe infectious hepatitis in whom, on the average of three years from the subsidence of jaundice, peritoneoscopy and biopsy revealed significant cirrhotic changes. The authors believed that "there is a definite relationship of prolonged severe infectious hepatitis to a 'chronic latent hepatitis' and to actual cirrhosis, despite some opposing opinions."

The solution to the problem of the relation of cirrhosis to viral hepatitis appears to lie in the long-term studies of military personnel involved in epidemics of this disease being conducted by the Veterans Administration. The investigation of histories of patients with fully established cirrhosis is of questionable value inasmuch as their original illness is of uncertain etiology.

Little is known at present of the presence of virus in the patient with chronic hepatitis. Numerous blood banks refuse as donors volunteers with a past history of jaundice, others accept as donors volunteers who have had no history of jaundice during the preceding six months or a year. There is no scientific basis for either choice since little is known regarding the maximum period during which the patient with infectious hepatitis or homologous serum jaundice may act as a carrier of hepatitis virus. If such knowledge were available, the fact that either type of disease may occur without visible jaundice makes the task of refusing as donors volunteers with a past history of hepatitis a formidable one indeed. During the past year one study was conducted to determine the presence of virus in patients with chronic hepatitis.<sup>29</sup> Feces, serum and liver-biopsy material collected from patients with chronic hepatitis three to twelve months after the onset of their disease were administered orally to volunteers. Several of the men developed mild to moderate illness after ingestion of the feces and liver preparations, no illness resulted from the ingestion of serum. Although the illnesses were frequently suggestive of hepatitis, the absence of confirmatory laboratory findings makes definite conclusions regarding the persistence of the virus in the materials studied impossible, and further studies will be necessary.

#### *Mode of Transmission*

Although several modes of spread of the virus of infectious hepatitis have been suggested, there has been no proof favoring any one method of transmission with the exception of spread through contaminated drinking water. Numerous outbreaks reported in the literature do not, however, appear

to be explained by the ingestion of contaminated water, and contact and respiratory spread still seem likely. Trussell<sup>30</sup> has recently reported an outbreak in military personnel that he regards as suggesting transmission of the virus by flies or by food handlers, utensils, dishwater and food. Anderson,<sup>31</sup> in reviewing infectious hepatitis in Iceland, where the disease has been four times greater in rural than in urban areas, attributed the difference to the poor disposal of excreta in the rural areas. He believes that in Iceland the infection is spread by dust-borne dried excreta. Harrison<sup>32</sup> has reported an outbreak that appeared to originate from a polluted well but offers no direct proof of this method of spread of the disease.

### *Virus Strains*

The reports from Denmark during the past year of a malignant form of hepatitis<sup>33, 34</sup> again raise the possibility that there are various strains of infectious hepatitis virus. The outbreaks in Denmark have involved primarily women past the menopause, with a mortality of 50 to 61 per cent. The duration of the illness was four to nine months, a period much longer than that of infectious hepatitis seen in other parts of the world. In addition, evidence of portal obstruction in the form of ascites and edema was striking in these patients, and there was widespread destruction of liver cells, with replacement by fibrous tissue in the chronic cases. Infectious hepatitis as observed in this country and Europe occurs primarily in children and young adults, hence its relation to the malignant hepatitis seen in Denmark is obscure. Whether or not malignant hepatitis is due to a virus remains to be determined, as does its relation to infectious hepatitis.

Stokes and Miller<sup>35</sup> have reported an outbreak of severe infectious hepatitis in Burma with a mortality of 20 per cent, and raise the question whether the higher mortality is due to an increase in virulence of the virus. The importance of the state of nutrition of people involved in an outbreak as a determining factor in the severity of the disease still remains to be determined, though these authors believe the higher mortality cannot be explained on a nutritional basis, but is due to increased virulence of the virus.

### *Infectious Hepatitis in Pregnancy*

Martin and Ferguson<sup>36</sup> have reported 4 cases of infectious hepatitis in pregnant women, 2 of whom had prolonged periods of jaundice. According to these writers hepatitis has been infrequent during pregnancy. There were no deaths in the mothers, and the 2 deaths in the offspring could not be attributed to the maternal disease. The authors believe that interruption of pregnancy should be considered if the patient's disease is severe and suggest the prophylactic use of gamma globulin in pregnant women exposed to the disease.

Zondek and Bromberg<sup>37</sup> have recently recorded 29 cases of infectious hepatitis occurring during pregnancy. Five women died of acute liver atrophy, and 2 developed chronic hepatitis. These writers found that premature deliveries were frequent in the women with severe hepatitis but that no effect on the fetus could be demonstrated. All the severe and fatal cases occurred during the latter part of the second half of pregnancy in women with poor nutrition. In contrast to Martin and Ferguson, Zondek and Bromberg believe that the clinical course of the disease is aggravated after spontaneous abortion, and therefore argue against the artificial interruption of pregnancy. Decrease in blood urea and a positive estrone clearance test indicated severity of the disease more successfully than other tests of liver function. The authors were unable to determine a correlation between intensity of jaundice and severity of the clinical course.

### *Treatment*

To date, no therapy has clearly affected the course of acute infectious hepatitis other than bed rest and a high-protein diet. Kunkel<sup>1</sup> has emphasized the value of a high-protein, normal fat and normal-carbohydrate diet in the treatment of infectious hepatitis; he believes that the low-fat diet is very unpalatable and hence causes a fall in caloric intake. Jones and Volwiler<sup>38</sup> similarly maintain that a rigid restriction of fat is unwise in the treatment of hepatitis and point out that "when protein intake is maintained at a high level, there is as yet no real evidence that a moderately high fat intake will harm the liver or enhance toxic injury."

No definite value can be attributed at present to the use of methionine, choline chloride, liver extract or vitamins in the therapy of infectious hepatitis.<sup>39</sup> Hanger et al. believe that normal human serum albumin administered to patients with severely damaged livers and ascites and edema is beneficial.

There appears to be almost universal acceptance at present of the importance of bed rest in acute infectious hepatitis.<sup>39</sup> Klatskin and Rappaport,<sup>40</sup> as stated above, failed to find any correlation between lack of bed rest and persistence of signs and symptoms of chronic hepatitis, but the experience of most investigators has shown a definite relation between the early return of patients to full activity and the recurrence or persistence of signs and symptoms of hepatitis. Infectious hepatitis is a disease comparable to rheumatic fever; the patient should continue bed rest not only until the signs and symptoms of the disease have disappeared but also until most of the laboratory tests for liver dysfunction have returned to normal. Such tests must be weighed with caution; the persistence of an abnormal bromsulfalein retention is of much greater significance than a positive thymol-flocculation test.

Since the latter may persist for a long time after this disease and its exact significance is as yet unknown, it appears unwise to insist on bed rest until this test reaches normal. As in rheumatic fever the return of a patient to full activity should be graduated and should be accompanied by clinical and laboratory investigation for evidence of recurrence of liver dysfunction.

### Prevention

Although gamma globulin is of great value in the prevention of infectious hepatitis, its practical use is limited to outbreaks of the disease in institutions and camps and in the rare family such as the one described by Kunkel and Hoagland,<sup>8</sup> in which several members developed the disease. Since infectious hepatitis during childhood is mild the use of gamma globulin to prevent the disease in normal healthy children might well be open to question. There can be no disagreement, however, concerning its use in pregnant women or in adults and children with various types of chronic disease. Even in this group its value is limited owing to the fact that exposure to hepatitis without jaundice may occur and not be recognized.

In view of the several possible methods of spread of the virus, real control of infectious hepatitis will be achieved only when a vaccine becomes available. Until that time methods for the prevention of spread of the disease must be sought. Neefe and his associates,<sup>40</sup> who in the past have stressed contaminated drinking water as the means of spread of the virus agent, have extended their studies of the action of chlorine on the virus of infectious hepatitis. They have found that a thirty-minute residual total chlorine concentration of one part per million was effective in inactivating the virus in water that had been coagulated, settled and filtered but was ineffective when employed in previously untreated water. They have not yet determined the minimal effective dose of chlorine in coagulated, settled and filtered water, as a result the efficacy of modern municipal methods of water treatment against this virus is still unknown.

### HOMOLOGOUS SERUM HEPATITIS

The majority of the work on homologous serum hepatitis reported during the past year and a half comprises studies on the incidence of jaundice after transfusion with pooled plasma. The Committee on Blood and Blood Derivatives of the Advisory Board on Health Services of the American National Red Cross has emphasized the potential risk to patients in the administration of pooled plasma, recommending instead the use of whole blood or normal human serum albumin. During the past year Brightman and Korns,<sup>41</sup> in a follow-up study of patients transfused with pooled plasma, have

reported a 4.5 per cent incidence of homologous serum jaundice. Rosenthal<sup>42</sup> found that 4.08 per cent of the patients in his study developed jaundice after transfusion with plasma or plasma and whole blood. No patient receiving whole blood alone developed homologous serum hepatitis. Scheinberg, Kinney and Janeway,<sup>43</sup> in investigating jaundice following plasma and blood transfusions at the Peter Bent Brigham Hospital, estimated that 1 case of jaundice occurred in every 86 transfusions.

All such studies to date reveal that the use of pooled plasma provides a real danger and should be avoided whenever possible. No investigation has yet been made regarding the incidence of hepatitis without jaundice after transfusion with whole blood or blood products, and it is extremely likely that the true incidence of homologous serum hepatitis is higher than present studies indicate.

### "Syringe" Jaundice

The transmission of hepatitis virus by means of improperly sterilized syringes and needles is now well established. During the past year several additional reports of jaundice transmitted by syringe were published.<sup>44-45</sup> Truelove and Hogben<sup>46</sup> found that approximately 50 per cent of syphilitic patients started on arsenical treatment in certain British military venereal-disease centers developed jaundice, when syringes were sterilized by boiling, the incidence of jaundice fell to about 5 per cent. Turner<sup>47</sup> reported a series of cases of what appeared to be homologous serum jaundice after penicillin injections in which syringes were not sterilized between patients but sterile needles were employed. Capps, Sborov and Scheiffley<sup>48</sup> described an outbreak of hepatitis apparently due to transmission of virus by syringes. One hundred and ten men received an intramuscular injection of tetanus toxoid, the material was administered from 10-cc syringes containing ten doses each, and needles were changed between patients. The authors estimated that at least 20 per cent of the men developed acute infectious hepatitis. The incubation period varied from 21 to 38 days in 21 men and was 15 and 16 days respectively in 2 others. Because of the short incubation period, the authors concluded that they were dealing with the epidemic virus of infectious hepatitis. The possibility that this was a spontaneous outbreak of infectious hepatitis and not disease transmitted by syringe cannot be excluded. Ninety-one per cent of the cases had no jaundice, the laboratory findings on which the diagnosis of hepatitis without jaundice were based were frequently borderline, and the diagnosis in a number of these men is therefore open to question.

Chalmers<sup>49</sup> presented an interesting study of jaundice in patients with malaria induced by blood

inoculation. He found that of 450 patients treated with malaria 36 developed jaundice and that only half of these had their jaundice during the attack of malaria. He speculates on the possibility that these delayed cases of jaundice are due to homologous serum hepatitis.

### *Clinical and Pathological Studies*

Several clinical and pathological reviews of homologous serum hepatitis have been published during the past year<sup>49-53</sup> but little has been added to the literature previously reported. Klatzkin and Rappaport<sup>54</sup> describe the cases of 2 patients who, during convalescence from homologous serum hepatitis, developed bilateral gynecomastia. In 1 case the enlargement developed seven weeks after onset of the disease when jaundice had largely subsided, and in the other fourteen weeks after onset. Gynecomastia is not a rare finding in cirrhosis of the liver and is thought to be due to the resultant hyperestrinemia. The authors believe that though both patients had unusually severe and protracted jaundice, there was no evidence of the development of cirrhosis.

### *Epidemiologic Studies*

Gauld<sup>55</sup> has reported an interesting study of homologous serum jaundice and infectious hepatitis in Army personnel in the Mediterranean Theater of Operations. He found that men who had had an attack of homologous serum jaundice (from yellow-fever vaccine) had less immunity to infectious hepatitis than men with no previous jaundice. In addition, soldiers who had contracted infectious hepatitis appeared to develop an immunity to subsequent development of infectious hepatitis. These studies are in accord with human experiments in the past, which indicate that there is no cross-immunity between homologous serum hepatitis and infectious hepatitis.

McKinlay and Truelove,<sup>56</sup> in similar studies conducted among Canadian and New Zealand troops stationed in Italy, found that in these men the incidence of homologous (post-arsphenamine) serum jaundice, unlike infectious hepatitis, was uninfluenced by age and had no striking seasonal variation. They also determined that previous attacks of infectious hepatitis conferred no immunity to homologous serum jaundice and concluded that the two diseases were caused by different viral agents.

Aycock and Oren<sup>57</sup> have published an interesting study of infectious hepatitis and homologous serum hepatitis. They argue that the virus of homologous serum hepatitis has a long incubation period because it enters the body with serum that may contain antibodies and thus prolong the incubation period, whereas in infectious hepatitis the virus

(from feces or nasal secretions) enters free of such antibodies, resulting in a short incubation period. They believe that analogous studies in poliomyelitis and influenza suggest that the two viruses of infectious hepatitis and homologous serum hepatitis are not different entities and that infectious hepatitis serves as the "virus reservoir" for homologous serum hepatitis. Although the results of experimental studies in volunteers with these viruses are not in accord with the views of Aycock and Oren, it must be re-emphasized that the work with volunteers has of necessity been limited, requiring further confirmation before definite conclusions regarding the relation of the viral agents can be reached.

### *Homologous Serum Hepatitis in Infancy*

During 1947 the first cases of homologous serum hepatitis in infants were reported. Three infants developed the disease after plasma transfusions,<sup>41, 43</sup> and a fourth after blood transfusion.<sup>58</sup> Two infants died with necrosis of the liver. Karelitz<sup>59</sup> has reported 6 infants who developed homologous serum hepatitis, 5 after plasma transfusion and 1 after whole-blood transfusion. Four patients in his series died of acute liver necrosis. Although the danger of homologous serum hepatitis after whole-blood transfusion is far less than that of hepatitis after pooled-plasma transfusion, the occurrence of this disease in 2 infants with erythroblastosis fetalis treated with replacement transfusion emphasizes the increasing risk with multiple transfusions.

Scott and Tovey<sup>61</sup> reported a case of homologous serum hepatitis in a young mother who received two bottles of plasma and one of blood at the time of delivery. Although she developed jaundice seventy-nine days later, 2 infants whom she had been nursing (her own and that of a neighbor) did not develop the disease. It is of interest to speculate on the possibility that the virus of homologous serum hepatitis passes into the breast milk. However, if virus were present in breast milk, it is unlikely that disease would result in nursing infants since experimental work with human volunteers appears to show that the virus of homologous serum hepatitis is ineffective when administered orally.

### *Prevention of Homologous Serum Jaundice*

Because of the value of gamma globulin in the prevention of infectious hepatitis, investigations of its use in the prophylaxis of homologous serum hepatitis naturally followed. Although initial studies indicated that gamma globulin was effective as a method of prevention, two reports published in 1947 failed to confirm the earlier findings.<sup>41, 62</sup> Duncan et al.<sup>62</sup> believed that the discrepancy in the findings might be explained by the fact that two injections of globulin thirty days apart were given

in the earlier studies whereas in those reported during the past year only a single injection was administered. In view of the long incubation period of homologous serum jaundice it appeared possible that the passive immunity conferred by a single injection was of too brief duration. The use of gamma globulin in prophylaxis, though of practical value in military personnel, would be difficult to employ in the civilian population.

Much interest and hope is centered about the use of ultraviolet irradiation as a means of inactivating the virus of homologous serum hepatitis in blood and blood products since the report by Oliphant in 1944 indicating that such irradiation appeared of value. Although MacCallum failed to substantiate Oliphant's findings, the method appeared promising and worthy of further investigation. Wolf and his co-workers<sup>62</sup> have reported the administration of irradiated plasma to 21 persons without untoward reaction. They tentatively concluded that the irradiation of plasma appeared to be a safe procedure that will free plasma from the presence of active virus of homologous serum jaundice. These writers offer no evidence that the virus is inactivated, and studies investigating the incidence of homologous serum jaundice in patients receiving irradiated plasma will be awaited with much interest.\* Gellis et al.<sup>64</sup> have reported the use of heat in an attempt to ensure the inactivation of hepatitis virus in normal human serum albumin solution. Bird, Enders and Boyd<sup>65</sup> have shown that certain viruses (Theiler's mouse-encephalomyelitis virus, vaccinia virus, tobacco-mosaic virus and tobacco-necrosis virus) added to pooled plasma survived fractionation and were found in all fractions prepared from the plasma. It therefore appears possible that the hepatitis virus might similarly survive fractionation and appear in the albumin. Albumin solutions to which the virus was added, heated to 60°C for ten hours, failed to give rise to homologous serum hepatitis when injected into volunteers, whereas the injection of unheated mixture of albumin and virus resulted in hepatitis though without clinical jaundice. These writers did not determine the minimum degree of heating required to inactivate the virus. All albumin solutions are now heated at 60°C for ten hours as a routine procedure, on the basis of these limited studies albumin solution appears to be free of active hepatitis virus. This method can be applied to albumin owing to the fact that albumin solutions can be stabilized to withstand heating, but is not applicable to serum, plasma or whole blood.

\*Blanchard and his co-workers in a personal communication reported the successful inactivation of the virus of homologous serum hepatitis by ultraviolet irradiation of plasma. Their experiments were conducted on volunteers inoculated with plasma known to contain the viral agent.

inoculation. He found that of 450 patients treated with malaria 36 developed jaundice and that only half of these had their jaundice during the attack of malaria. He speculates on the possibility that these delayed cases of jaundice are due to homologous serum hepatitis.

### *Clinical and Pathological Studies*

Several clinical and pathological reviews of homologous serum hepatitis have been published during the past year<sup>49-53</sup> but little has been added to the literature previously reported. Klatskin and Rappaport<sup>54</sup> describe the cases of 2 patients who, during convalescence from homologous serum hepatitis, developed bilateral gynecomastia. In 1 case the enlargement developed seven weeks after onset of the disease when jaundice had largely subsided, and in the other fourteen weeks after onset. Gynecomastia is not a rare finding in cirrhosis of the liver and is thought to be due to the resultant hyperestrinemia. The authors believe that though both patients had unusually severe and protracted jaundice, there was no evidence of the development of cirrhosis.

### *Epidemiologic Studies*

Gauld<sup>55</sup> has reported an interesting study of homologous serum jaundice and infectious hepatitis in Army personnel in the Mediterranean Theater of Operations. He found that men who had had an attack of homologous serum jaundice (from yellow-fever vaccine) had less immunity to infectious hepatitis than men with no previous jaundice. In addition, soldiers who had contracted infectious hepatitis appeared to develop an immunity to subsequent development of infectious hepatitis. These studies are in accord with human experiments in the past, which indicate that there is no cross-immunity between homologous serum hepatitis and infectious hepatitis.

McKinlay and Truelove,<sup>56</sup> in similar studies conducted among Canadian and New Zealand troops stationed in Italy, found that in these men the incidence of homologous (post-arsphenamine) serum jaundice, unlike infectious hepatitis, was uninfluenced by age and had no striking seasonal variation. They also determined that previous attacks of infectious hepatitis conferred no immunity to homologous serum jaundice and concluded that the two diseases were caused by different viral agents.

Aycock and Oren<sup>57</sup> have published an interesting study of infectious hepatitis and homologous serum hepatitis. They argue that the virus of homologous serum hepatitis has a long incubation period because it enters the body with serum that may contain antibodies and thus prolong the incubation period, whereas in infectious hepatitis the virus

(from feces or nasal secretions) enters free of such antibodies, resulting in a short incubation period. They believe that analogous studies in poliomyelitis and influenza suggest that the two viruses of infectious hepatitis and homologous serum hepatitis are not different entities and that infectious hepatitis serves as the "virus reservoir" for homologous serum hepatitis. Although the results of experimental studies in volunteers with these viruses are not in accord with the views of Aycock and Oren, it must be re-emphasized that the work with volunteers has of necessity been limited, requiring further confirmation before definite conclusions regarding the relation of the viral agents can be reached.

### *Homologous Serum Hepatitis in Infancy*

During 1947 the first cases of homologous serum hepatitis in infants were reported. Three infants developed the disease after plasma transfusions,<sup>49, 58</sup> and a fourth after blood transfusion.<sup>59</sup> Two infants died with necrosis of the liver. Karelitz<sup>60</sup> has reported 6 infants who developed homologous serum hepatitis, 5 after plasma transfusion and 1 after whole-blood transfusion. Four patients in his series died of acute liver necrosis. Although the danger of homologous serum hepatitis after whole-blood transfusion is far less than that of hepatitis after pooled-plasma transfusion, the occurrence of this disease in 2 infants with erythroblastosis fetalis treated with replacement transfusion emphasizes the increasing risk with multiple transfusions.

Scott and Tovey<sup>61</sup> reported a case of homologous serum hepatitis in a young mother who received two bottles of plasma and one of blood at the time of delivery. Although she developed jaundice seventy-nine days later, 2 infants whom she had been nursing (her own and that of a neighbor) did not develop the disease. It is of interest to speculate on the possibility that the virus of homologous serum hepatitis passes into the breast milk. However, if virus were present in breast milk, it is unlikely that disease would result in nursing infants since experimental work with human volunteers appears to show that the virus of homologous serum hepatitis is ineffective when administered orally.

### *Prevention of Homologous Serum Jaundice*

Because of the value of gamma globulin in the prevention of infectious hepatitis, investigations of its use in the prophylaxis of homologous serum hepatitis naturally followed. Although initial studies indicated that gamma globulin was effective as a method of prevention, two reports published in 1947 failed to confirm the earlier findings.<sup>49, 62</sup> Duncan et al.<sup>62</sup> believed that the discrepancy in the findings might be explained by the fact that two injections of globulin thirty days apart were given

Since my report a year ago three former presidents of the Society have died Charles H Dolloff, Concord, Samuel T Ladd, Portsmouth, and Richard W Robinson, Laconia. At the time of his death Dr Ladd was a trustee.

In accordance with instructions from the House of Delegates the following measures have been carried out \$60 was given to the Cancer Committee, and \$100 was contributed for membership in the Council of the New England State Medical Societies. If we continue our membership in the Council the annual fee of \$100 will be due again this year. I have asked Dr Tuttle, who is reporting on the Council, to take this question up in his report.

The House of Delegates a year ago expressed disapproval of a barbiturate bill, which was submitted to the State Senate. Under this bill doctors could prescribe and dispense barbiturates only with the approval of the State Board of Pharmacy. This bill will presumably come up again next year, and unless it is materially changed in form it is my understanding that the members wish the Society to oppose it.

The Veterans Administration was notified that the Society approves the fee schedule and agreement for hometown care of veterans with service-connected dis-

abilities. This schedule and agreement must be renewed annually. It meets with the approval of the delegates. I shall sign and submit to the Veterans Administration the necessary papers each year until further notice.

Two new committees were added to our roster the Committee on Rural Health and the Committee on Industrial Health.

For the first time since the war we are giving gold medals to the men who have been members for fifty consecutive years. The Indiana Medical Society, instead of a medal, gives a button, which may be worn in the lapel. I have a sample button here this evening.

The round-table conferences have been increased to two-hour periods on the morning of each day.

The committee that arranged this annual meeting decided, for reasons described in a circular, to omit exhibits, the Committee also wished to have members of the Society present brief papers at the afternoon sessions. For this reason at these sessions we are having only four out-of-State speakers. The Committee sent postal cards to all members asking them if they would like to take part in the program this year. It was impossible to find a place on the program for all the members who replied in the affirmative. These postal cards have been kept, however, and will probably be used in the future if this type of program meets with approval.

The Women's Auxiliary has asked us to help it financially for its part in this meeting. Before the war it was our custom to give the Auxiliary \$100 annually. During the war this donation was not given. The House of Delegates thought we could not afford it because so many members were not paying dues. Now that the finances are in much better shape I recommend that the Auxiliary be given \$100 this year and annually until further notice.

Our attorney has asked for an increase in his retaining fee. Mr Sulloway investigates all cases in which suit is threatened against a doctor, he gives free consultation to any member of the Society who needs legal help on a medical problem, he covers all medical legislation that is submitted every other year in the Senate and the House of Representatives, he is a guide, philosopher and friend at all the meetings of the Advisory Committee on Jurisprudence, he settles all cases that in the opinion of this Advisory Committee should be settled, and he conducts the trials in cases that go to Court. It is interesting to note that since Mr Sulloway was appointed counsel some twelve years ago he has not lost a suit that, on recommendation of the Advisory Committee on Jurisprudence, has gone to trial. I recommend that Mr Sulloway's retaining fee be increased to \$200 annually until further notice.

The Connecticut State Medical Society has recently given medical students the privileges of the Society without charge. You may wish to make this friendly gesture in New Hampshire. Presumably, all it would mean would be that students of the Dartmouth Medical School could attend a meeting of a county society or of the State Society if they wished to do so.

An essay contest authorized last year has recently been completed. This contest was open to all students in high schools and junior high schools throughout the State. We received 105 essays. These were screened and the seven essays that seemed to be the best were submitted to the three judges. Most Reverend Matthew F Brady, Bishop of Manchester, Dr Edgar Fuller, Commissioner of Education, and President John A Hunter.

The first prize of \$100 was awarded unanimously by the judges to Miss Irene Moore, of Rochester. Two second prizes of \$50 each were awarded to Miss Violette Nadeau, of Cascade, and Mr Aristotle Bonras, of Newmarket. In addition, county prizes of \$10 each were awarded. The total outlay came approximately to the \$300 that was allotted by the House of Delegates for this contest, and we received from the contest a great deal of favorable comment from the newspapers throughout the State.

A weekly radio broadcast called "Doctors' Orders" has been on the air for the past few years in all the New England States except Vermont and New Hampshire. We have received overtures from the Yankee Network to put this program on in New Hampshire beginning next fall. A sponsor who must be approved by the Society is furnished by the network. ## NEW HAMPSHIRE MEDICAL SOCIETY

### PROCEEDINGS OF THE ONE-HUNDRED AND FIFTY-SEVENTH ANNIVERSARY

House of Delegates, June 1, 2 and 3, 1948

THE House of Delegates convened at Wentworth Hotel, Newcastle, on June 1, 1948, at 7 30 p m., with Speaker Donald G McIvor, presiding

The following members answered the roll call

The President, *ex-officio*  
 The Vice-President, *ex-officio*  
 The Secretary-Treasurer, *ex-officio*  
 Nathan Brody, Laconia  
 Reginald F DeWitt, Plymouth  
 W J Paul Dye, Wolfeboro  
 Francis J C Dube, Center Ossipee  
 Walter H Lacey, Keene, alternate  
 Albert C Johnston, Keene  
 Marjorie A Parsons, Colebrook  
 Francis M Appleton, Gorham  
 Leslie K Sycamore, Hanover  
 Leslie E McKinlay, North Haverhill  
 Everett C Campbell, Woodsville  
 Reginald K House, Hanover  
 Joseph N Friborg, Manchester  
 Robert E Biron, Manchester  
 Norman W Crisp, Nashua  
 Claire G Cayward, New Ipswich  
 Daniel J Sullivan, Nashua  
 Andrew L MacMillan, Concord  
 Francis Brown, Henniker  
 L Whittaker, Portsmouth, alternate  
 Donald W Leonard, Exeter  
 Fred Fernald, Exeter  
 A E Barecomb, Rochester, alternate  
 Edna Walck, Dover  
 B Read Lewin, Claremont  
 George C Wilkins, Manchester  
 David W Parker, Manchester  
 Deering G Smith, Nashua

Leslie K Sycamore (chairman), Joseph N Friborg and Fred Fernald To the Committee on Memorials and Communications, he appointed Drs Brown, Cayward and Moriarty To the Committee on Nominations, he appointed Drs Dye, Parsons, House, Crisp and Whittaker

On motion duly made and seconded, it was voted to omit the reading of the previous minutes, because of the publication of the proceedings

On motion duly made and seconded, it was voted to dispense with the reading of the reports of the councilors, since they will be published in the *Transactions*

The secretary-treasurer, Dr Carleton R Metcalf, presented his report as follows

The total membership on December 31, 1946 was 557, that on December 31, 1947, was as follows

PAID	
Belknap County	37
Carroll County	15
Cheshire County	32
Cooks County	26
Grafton County	75
Hillsborough County	165
Merrimack County	78
Rockingham County	58
Strafford County	41
Sullivan County	21
Not in County Society	2
	— 550

#### UNPAID

Members in service and delinquents	18
	— 41
	591

The Speaker declared a quorum present, and appointed the Credentials Committee as follows Drs Johnston, MacMillan and House To the Committee on Officers' Reports, he appointed Drs

annual meeting from the exhibitors, and that there was to be no such income this year. The Committee wondered what that was going to do to the balance on hand of \$1170.

The Secretary replied that the balance of more than \$1100 had been increased to about \$4000, so that there would probably be \$1500 or more on December 31 without exhibitors.

The Secretary then recommended that the House of Delegates consider the Earl Warren matter. He had thought of sending the information to the New Hampshire delegates to the Republican National Convention in Philadelphia that the president of the California Medical Society had stated that Governor Warren favors, or has announced that he favors, socialized medicine on a national level and wants to put it in the platform of the Republican Party.

Dr Sycamore observed that a recommendation would be brought in on the next morning.

The report of the Council of the New England State Medical Societies was then presented by Dr Ralph W Tuttle.

The Council has now finished its third year of service to the component state medical societies in bringing the different societies closer together in their relations, and at the same time presenting a program of education and information.

The October meeting was highlighted by guest speakers on the antivivisection situation in New England, a subject of vital importance to New England medicine if we wish to retain our place in medical research. There was also presented a discussion on the medical approaches in the treatment of alcoholism.

At our next meeting a public-relations conference was conducted with a sizable attendance from throughout New England. The main speakers were top men from the radio and press. The doctors were more or less put on the pan because of their aloofness and indifference to the public in general and to the press and radio in particular. Much publicity accrued to the Council from the meeting, as evidenced by news clippings from papers throughout the area.

A closer alliance with the New England States Dental Officers' Conference was effected by having members of that organization as our guests at the meeting in March at Boston, and with the president of the Council, Dr Arthur H. Ruggles, their guest speaker on the subject of medical-dental relations, at their annual session at Hartford in April.

At our annual meeting in April it was brought to our attention that the American Public Health Association was holding a meeting in November, and that the New England Health Institute was to be held in Amherst, Massachusetts, from June 16 to 18, under the auspices of the Massachusetts State Department of Health. It was generally agreed that an effort should be made to have the Council actively connected with the health institute another year, if it is possible for such a relation to be effected.

The general appeal and effect on public relations of the radio program "Doctor's Orders" were discussed.

There was a discussion on medical organization for a national emergency. We already have such a committee in New Hampshire, and the other states are contemplating such committees.

There is a bill before Congress providing that physicians up to forty-five years of age could be inducted. The many telegrams from the state medical societies threatened to defeat the plan. But the armed service group are quite adamant. The Navy is not particularly concerned because most of its doctors are subject to recall. The armed

service group feels that it would have an immature group if only physicians under twenty-six were drafted.

There was considerable inquiry directed to hospitals in New England regarding general practitioners, and what standing they should have on the services of general hospitals.

In an effort to determine the privileges and restrictions regarding practice in the hospitals in New England by general practitioners, an inquiry was sent to fifty hospitals in the region. Replies were received from twenty-seven, including at least one from each of the New England states. Some of the large hospitals evaded the question. The tendency is toward concentration in specialties for staff privileges, with the specific criterion qualification by one of the various boards or colleges. Very few give the general practitioner much opportunity to render care for the majority of his patients.

This suggestion appears worthy of the consideration that the Council establish a committee of its own, or for it to make a complete study of the situation in the New England area to rationalize in this region what might be done in the best interests of the public and the medical profession, to give the general practitioner hospital privileges.

It is my opinion that the Council of the New England State Medical Societies is doing a worthwhile job in the interests of medical practice and general welfare, and I suggest to the House of Delegates that the usual sum of \$100 be appropriated to continue the work of the Council.

This motion was duly seconded and was carried. President John A. Hunter then spoke as follows:

Your president wishes to take this opportunity to give a brief account of his stewardship for the year 1947-1948, which, although nothing spectacular was accomplished, seems on the whole to have been a busy one.

In the beginning, Dr Metcalf was ill for some time, and later went away to convalesce, and you can well realize what this meant to an incoming officer, since our efficient secretary knows the ropes so well and handles the maze of details connected with this organization. However, with Mrs. Oulette's assistance and good counsel from ex-president Ralph Tuttle, we got the ball rolling.

The Scientific Committee held two lengthy meetings at the Eagle Hotel and Dr. Metcalf's office, planning the program for our annual meeting, and the majority concluded that we would eliminate the exhibits this year, the reasons for this decision having been mailed to each member with his program, and we trust that the experiment will work out satisfactorily.

Five counties invited the President to attend one or both of their meetings, and three such visitations were made, illness and weather conditions preventing attendance at the other two. Members of two of these societies brought their wives to the banquet, and afterward the ladies had a meeting of the auxiliary. It seemed to work out very bappily, with fine attendance.

In March I was appointed director of the Blue Cross and Blue Shield, and many long hours were spent at Concord revising the fee list, in an effort to get the organization out of the red. I never realized before the amount of work the officials and directors put into this organization, and in passing I ought to mention Drs. Harwood, of Burlington, Vermont, and Johnson, of St. Johnsbury, Vermont, who drove so far in miserable weather and stayed with us late into the night on more than one occasion, working out the new program.

I attended the March meeting of the New England Medical Council held at the Copley Plaza in Boston on March 7, which was a most interesting meeting. Public relations was one of the main subjects discussed by the editors of a large and a small newspaper. In the discussion that followed, it was pointed out that often the paper did not get the information correct, exploited a doctor's name and so forth, but the editors and some members present felt it was time for the doctors to come out of their citadel.

I attended an informal meeting at the Eagle Hotel in February, called by Secretary Metcalf, to hear Edward F.

takes part in the broadcast each week. There is no expense to the Society. I have referred this matter to the Committee on Communications and Memorials and have asked them to report and make a recommendation at this meeting.

Last February I received a telephone call from Chicago from Mr. Stegen, an associate director of the National Physicians Committee. Mr. Stegen, who said that he was coming to New Hampshire, wanted to know if I would invite a small group of members from the Society to confer with him about legislation and the part therein played by the National Physicians Committee. This meeting with Mr. Stegen, with 15 or 20 members of the Society in attendance, was held at the Eagle Hotel in Concord on the evening of February 19.

The National Physicians Committee wants us to form an informal group to co-operate more closely with it. We have, of course, been doing this to a certain extent for several years through some of our county societies.

The members of the Society who met in Concord on February 19 approved the formation of a State committee on the following basis:

Such a group in New Hampshire would be informal. It would not join the National Physicians Committee. It would receive their literature and could get advice on legislation if it wished such advice. The State group would not be bound by any opinions, plans or activities of the National Physicians Committee, and would be free to criticize or advise this Committee if the Committee seemed to be off the track.

I recommend that you approve the appointment of an informal committee without placing the Committee officially on the list of standing committees. If your approval is forthcoming several members have agreed to serve.

Before the war we used to send delegates to the annual meetings of the other state medical societies in New England. Some of the delegates from New Hampshire enjoyed these trips, occasionally, delegates felt that they were not very warmly received in other states. This procedure was omitted during the war because of the difficulties of travel. Do you wish again to send delegates or shall we let the procedure remain in status quo?

The *New England Journal of Medicine* has found it necessary to increase the subscription rate for our members who wish to receive all the fifty-two issues of the *Journal* each year. The Society pays the *Journal* \$1.00 a year for each member, and for this the member receives twelve copies annually. Hereafter any member who wishes to receive fifty-two copies annually must send, individually, \$3.00 to the *Journal*, in addition to the \$1.00 that is sent by the Society.

On April 5 and 6 Dr. Daniel J. Sullivan, chairman of the Committee on National Emergency Medical Service, attended a meeting in Chicago, which considered the medical needs in the event of another national emergency. This meeting was sponsored by the American Medical Association, and several top officials from the federal Government were present.

There seem to be three hotels in New Hampshire that can accommodate a convention as large as ours where many who attend wish to stay overnight. These hotels are the Hotel Wentworth in Newcastle, the Mount Washington Hotel, in Bretton Woods, and the Mountain View House, in Whitefield.

On motion duly made and seconded, it was voted that the report of the Secretary-Treasurer be referred to the Committee on Officers' Reports.

Dr. Sycamore, for the Committee on Officers' Reports, recommended that the House of Delegates stand in silent tribute to the memory of Charles H. Dolloff, Samuel T. Ladd and Richard W. Robinson.

This motion was duly seconded and was carried.

Dr. Sycamore then recommended that the Committee on Public Relations be instructed to oppose any barbiturate bill that might be introduced into

the New Hampshire General Court, similar to the bill that the House of Delegates disapproved at its 1947 session.

This motion was duly seconded and was carried.

Dr. Sycamore also recommended that the Secretary be instructed to renew the agreement between the New Hampshire Medical Society and the Veterans Administration regarding hometown care of veterans, renewal to be made each year until further notice.

This motion was duly seconded and was carried.

Dr. Sycamore then stated that it did not appear too clear just what the functions of the Women's Auxiliary were, if it is to be of aid and assistance to the Society, it should stand on its own feet and pay its own way.

Dr. Metcalf stated that the money was used largely for a party that was held each year. The Auxiliary also contributed to the Benevolence Fund by giving parties and engaging in other home activities.

Dr. Leonard then remarked that the ladies paid \$1.00 a year, of which fifty cents went to the national organization.

Dr. Dye moved that the Women's Auxiliary be given \$100.

This motion was duly seconded and was carried.

Dr. Sycamore then moved that the retainer fee for Attorney Frank J. Sulloway be increased to \$200.

This motion was duly seconded and was carried.

Dr. Sycamore recommended that the House of Delegates approve the appointment of an informal committee to co-operate with the National Physicians Committee.

This motion was duly seconded and was carried.

The secretary read the names of this committee, as follows: Drs. Miller and Smart, of Belknap County; W. J. Paul Dye, of Carroll; Johnston and Almqvist, of Cheshire; Marjorie Parsons, of Coos; Campbell, Sycamore and House, of Grafton; Smith and Powers, of Hillsborough; Graves, Blood, Brown and Metcalf, of Merrimack; Leonard, of Rockingham; Hunter and Walch, of Strafford; and Lewin, of Sullivan.

The Speaker then asked if the House of Delegates approved this committee. There was a unanimous answer in favor of approval.

Dr. Sycamore then moved that no official delegates be appointed to attend the meetings of the medical societies of the other New England states. After some discussion, the motion was duly seconded and was carried.

Dr. Sycamore recommended that the next annual meeting be held at either the Mount Washington Hotel or the Mountain View House. After some discussion consideration of the matter was postponed until the last day of the meeting.

Dr. Sycamore then remarked that last year there had been an item of \$1000 net received from the

This motion was duly seconded and was carried. The report of the Committee on Medical Economics was then presented by the chairman, Dr Leslie K. Sycamore.

The Committee reports with deep regret the loss by death of one of its members. Dr Richard W. Robinson has been a member of the Committee for many years, and always took a keen and active interest in the problems with which the Committee was concerned. His consideration of any question was characterized by a penetrating insight into its implications, coupled with an uncompromising loyalty to the highest ideals of his profession and a sympathetic concern for the best interests of the patient. The members of the Committee experienced a keen sense of personal loss in the passing of a friend. The Committee is the poorer for the lack of his wise and kindly counsel, and the New Hampshire Medical Society has lost one of its ablest and best-loved leaders.

#### *Welfare Fee Schedule*

At the last session of the House of Delegates, the Committee was instructed to investigate the possibility of obtaining increased fees for services to welfare patients. Accordingly, an interview was arranged with Mr Elmer Andrews, commissioner of public welfare, who stated that any change would be impossible during the current biennium, because no funds were available in the appropriation for meeting any increase. He suggested that representation should be made at the budget hearing to be held in the fall by the Board of Public Welfare. The Committee plans to take this action.

#### *New Hampshire—Vermont Physician Service*

Several significant developments have occurred during the year regarding the Blue Shield program. Enrollment has steadily increased and has reached 170,000 for the Surgical Division and 85,000 for the Medical Division; gross income has reached a rate of \$1,500,000 per year. This places us high on the list of nonprofit medical-society plans.

On the other side of the picture, however, there has been over the past fifteen months a steadily rising utilization of service, from 220 to 275 cases per 1000 participants with some indication at present that this trend is leveling off. From the medical viewpoint, this may be considered an indication that the Service is better achieving its aim of making medical care more widely available. From the actuarial viewpoint, however, this increased utilization has exceeded the anticipated load and has resulted in a serious operating deficit in the Surgical Division amounting in the first three months of 1948 to the sum of \$60,000, or 23 per cent of income. The Board of Directors has deemed it necessary, therefore, to make a substantial increase in the premium rates to meet the deficit and to provide a reasonable surplus for reserves. Utilization in the Medical Division has also increased, but has not exceeded a satisfactory loss ratio.

Obviously, there must be a point beyond which any increase in premiums will result in a decrease in enrollment, and will result also in putting Blue Shield in an unfavorable position from competition from commercial insurance companies. Where that point lies, we are not at present in a position to predict. The situation does raise the question whether any of the increase in utilization is unnecessary in the sense that procedures employed are not essential in diagnosis or treatment. This admittedly is a very difficult line to draw, especially in the face of pressure from the patient, who wants to "get his money's worth" from his insurance. If any overuse does exist, each physician can assist in discouraging it by pointing out to the patient that each item of service enters into the cost to the subscriber.

Another area in which the individual physician can be of help to the Service is in the more accurate definition for the Claims Department of the pre-existing conditions that come under the exclusion clause in the contract and in an explanation to the patient that such exclusions are necessary to prevent overloading the service with chronic conditions, and to prevent a subscriber from joining for

a brief period for the sole purpose of obtaining treatment for a known condition.

Particularly in view of the increase in premium rates, it behooves us as members of the New Hampshire Medical Society to remind ourselves of the conditions under which the New Hampshire Physician Service was constituted under the aegis of the Society. To avoid the complications of a service contract with an income limit for the subscriber, it was decided to get up the program on an indemnity basis, but at the same time to protect the low-income subscriber by mutually agreeing that in this subscriber group the fee charged should approximate the benefit listed in the schedule. The low-income group comprises roughly individual incomes up to \$2500 per year, and family incomes up to \$3500 per year. For such subscribers, therefore, the fee in the average case should not exceed the benefit allowed.

In the national field, an important development has been the appointment of Dr Paul R. Hawley, formerly of the Veterans Administration, as chief executive officer of the Blue Shield and Blue Cross National Organizations. A joint session of the Blue Shield and Blue Cross representatives was held this spring to discuss plans for the formation of a National Blue Cross-Blue Shield Association to co-ordinate the activities of the various local plans. Final action has not been taken on this proposal.

The American Medical Association has taken the incomprehensible action of cancelling its Blue Cross coverage for its employees and placing its insurance with a commercial carrier. Your committee considers this action a betrayal of the nonprofit plans set up under medical-society sponsorship, and therefore recommends the adoption of the following resolution.

Whereas, the American Medical Association has urged its component Medical Societies to establish nonprofit Medical insurance programs as the doctor's answer to the problem of distribution of medical care, and

Whereas, the American Medical Association has cancelled its Blue Cross coverage of its employees in favor of a commercial carrier, and

Whereas, this action represents a betrayal of the principle of nonprofit voluntary sickness insurance, which is the foundation of the medical-care plans sponsored by the component societies, therefore be it

*Resolved* that the New Hampshire Medical Society strongly disapproves of the action of the American Medical Association in cancelling its Blue Cross coverage and urges that the contract with Blue Cross be renewed.

The Committee is firmly convinced that the Blue Shield program is performing a valuable service both for the patient and for the physician, and therefore continues to merit the full support of the members of the New Hampshire Medical Society.

Dr Sycamore moved that the Committee on Medical Economics be instructed to continue its negotiations with the State Board of Public Welfare regarding the welfare fee schedule.

The motion was duly seconded, and was carried, with one dissenting vote.

Dr Sycamore then moved that the House of Delegates recommend to the members of the New Hampshire Medical Society that their full support be given to the New Hampshire-Vermont Physician Service.

This motion was duly seconded and was carried.

Dr Sycamore further moved that the proposed resolution regarding the American Medical Association and Blue Cross be adopted, and that the Secretary be instructed to forward a copy to the Secretary of the American Medical Association.

Dr Sullivan asked why the American Medical Association had changed the procedure.

Stagen, of the National Physicians Committee, who presented legislative problems concerning medicine as we wish it practiced today, and hoped that a group from New Hampshire would be willing to lend their assistance, by communicating with their legislators, should national-emergency legislation arise. A letter from the Secretary to county secretaries explains our attitude in this matter.

A communication from Howard B. Sprague, M.D., was received asking for support for the New England Heart Association. I replied that no action, if any could be taken until after the House of Delegates had met on June 1. I trust that you gentlemen will make some decision so that the Secretary can give Dr. Sprague an answer.

In October I attended a get-together at Greenfield, New Hampshire, of many people in different walks of life who were interested in the Crotched Mountain project for rehabilitation of the crippled children of New Hampshire, and subsequently was present at the banquet in Manchester Armory when the drive was officially launched, Governor Thomas Dewey being the main speaker.

In conclusion I wish to thank everyone who helped make the year a success, and trust we will have an interesting scientific program the next two days, and a wealth of good fellowship.

Dr. Francis Brown then presented the report of the Committee on Memorials and Communications, as follows:

A communication from Mr. Frank Jones, of Providence, Rhode Island, suggests that the Society approve the radio program "Doctor's Orders" as a public-service program entitled to participation by local doctors. "Doctor's Orders" consists of weekly interviews with local physicians, presented from scripts prepared by the broadcasting companies subject to revision by the man presenting the material. Sample interviews included in the correspondence contain no particularly controversial matter. However it is not stated what the approval of the Society would be taken to mean in the way of responsibility. Because of one incidental reference to Society officers who must line up the speakers, the Committee assumes that the Society would be expected to undertake this function. The question of financial sponsorship is not involved in our approval. During the 1947-1948 season the program is said to have been approved by all the New England state medical societies except ours.

While realizing that public relations are becoming a more and more important function of medical societies, the Committee nevertheless submits the following considerations:

That it is questionable whether any New Hampshire radio station carries a sufficiently wide appeal throughout the State to make the proposal of much value as advertising for the Society.

That if our approval involves the responsibilities for providing the speakers, probably the entire load would be carried by members in Manchester, both for speaking and for finding the speakers. It is doubtful if any other city has enough physicians to make the program feasible.

That if any county society wishes to undertake such a responsibility, the approval of the Society would be superfluous.

We therefore recommend that approval of "Doctor's Orders" by the New Hampshire Medical Society be withheld.

After considerable discussion Dr. Brody moved that the broadcasting setup be approved and that the supervision of this medical broadcasting for the Society be by Dr. Brown, chairman of the Committee on Communications and Memorials.

Dr. Dye suggested the amendment that Dr. Brown be appointed on that Committee of Public Relations, so that he could supervise the program from there and consult with other members of the Committee from time to time, the other members

of the Committee being the President, the Vice President and Secretary-Treasurer.

Dr. Brody accepted the amendment to the motion.

The motion was carried.

The Report of Committee on the Control of Cancer was then presented.

On April 28, 1948, the third annual Cancer Conference Day, conducted by the Committee, was held at the Carpenter Hotel in Manchester. This meeting appeared to be a very successful one from the viewpoint of attendance, interest and the quality of the talks. The subjects presented by the three guest speakers from Boston and the five New Hampshire men were all on various aspects of cancer diagnosis or treatment, and the talks were well discussed by the audience. A luncheon was given at noon. All the expenses of the meeting were assumed as usual by the New Hampshire Division of the Field Army of the American Cancer Society. We only regret that more members of the New Hampshire Medical Society did not attend this meeting.

The Field Army has continued its excellent work in lay education, transportation of patients to clinics, making of surgical dressings for indigent patients and keeping together its large and enthusiastic membership. It has also continued its work in high-school cancer education.

During the year, as usual, three letters on pertinent cancer subjects have been mailed to each member of the Society. One on "Carcinoma of the Colon" gave suggestive symptoms, particularly the early symptoms, and advice regarding what should be done, including x-ray and protoscopic examinations in suspected cases. The usual warning of the importance of early rather than late examination was stressed. The second letter discussed the increasing lay criticism of the medical profession for its apparent inability to recognize cancer or the possibility of cancer early enough for the patient to be cured. These criticisms have appeared in medical journals as well as in lay magazines, and some criticisms were unjust and some were deserved. This letter admitted the inadequate examinations of some doctors but urged more careful examinations and suggested methods for carrying out such a program. It also stated that the patient who fears cancer should be examined as carefully as one fearing heart disease, stomach ulcer or gall-bladder disease. The third letter discussed cancer of the larynx in its two anatomic locations and stressed the importance of the early symptoms of persistent hoarseness and dysphagia. Any patient with such symptoms should be examined by a laryngologist as early as possible, and if cancer is found, the patient should have immediate treatment, either operation or x-ray therapy.

The functions of the cancer clinics have continued as usual, although the ones at Littleton and Nashua have been discontinued on account of lack of patients. There has been an increase in the number of patients entering the clinics during the past year, and the expenses of the Cancer Commission in caring for needy patients with cancer have increased quite considerably because of the increase in hospital rates. The American Cancer Society in its April issue of *Cancer News*, devoted the entire issue to the subject of cancer clinics, and honored the State by describing it as a model for other states, partly because we are the only state in the union having one clinic for every 50,000 people. A very full description of the functions of the Cancer Commission and the cancer clinics was given in the text, and it was accompanied by a group of photographs taken in one of the New Hampshire clinics. The Committee has expended \$52.31 of the \$60.00 appropriation, and requests the sum of \$60.00 for the next year's expenses.

GEORGE C. WILKINS, Chairman  
GEORGE F. DWIGELL  
RALPH E. MILLER  
WALTER H. LACEY  
ALBERT OPPENHEIMER

Dr. Sycamore moved that the sum of \$60 be appropriated for the expenses of the Committee on the Control of Cancer for the current year.

This motion was duly seconded and was carried. The report of the Committee on Medical Economics was then presented by the chairman, Dr Leslie K. Sycamore.

The Committee reports with deep regret the loss by death of one of its members Dr Richard W. Robinson has been a member of the Committee for many years, and always took a keen and active interest in the problems with which the Committee was concerned. His consideration of any question was characterized by a penetrating insight into its implications, coupled with an uncompromising loyalty to the highest ideals of his profession and a sympathetic concern for the best interests of the patient. The members of the Committee experienced a keen sense of personal loss in the passing of a friend, the Committee is the poorer for the lack of his wise and kindly counsel, and the New Hampshire Medical Society has lost one of its ablest and best-loved leaders.

#### *Welfare Fee Schedule*

At the last session of the House of Delegates, the Committee was instructed to investigate the possibility of obtaining increased fees for services to welfare patients. Accordingly, an interview was arranged with Mr Elmer Andrews, commissioner of public welfare, who stated that any change would be impossible during the current biennium, because no funds were available in the appropriation for meeting any increase. He suggested that representation should be made at the budget hearing to be held in the fall by the Board of Public Welfare. The Committee plans to take this action.

#### *New Hampshire — Vermont Physician Service*

Several significant developments have occurred during the year regarding the Blue Shield program. Enrollment has steadily increased and has reached 170,000 for the Surgical Division and 85,000 for the Medical Division, gross income has reached a rate of \$1,500,000 per year. This places us high on the list of nonprofit medical-society plans.

On the other side of the picture, however, there has been over the past fifteen months a steadily rising utilization of service, from 220 to 275 cases per 1000 participants with some indication at present that this trend is leveling off. From the medical viewpoint, this may be considered an indication that the Service is better achieving its aim of making medical care more widely available. From the actuarial viewpoint, however, this increased utilization has exceeded the anticipated load and has resulted in a serious operating deficit in the Surgical Division, amounting in the first three months of 1948 to the sum of \$60,000, or 25 per cent of income. The Board of Directors has deemed it necessary, therefore, to make a substantial increase in the premium rates to meet the deficit and to provide a reasonable surplus for reserves. Utilization in the Medical Division has also increased, but has not exceeded a satisfactory loss ratio.

Obviously, there must be a point beyond which any increase in premiums will result in a decrease in enrollment, and will result also in putting Blue Shield in an unfavorable position from competition from commercial insurance companies. Where that point lies, we are not at present in a position to predict. The situation does raise the question whether any of the increase in utilization is unnecessary in the sense that procedures employed are not essential in diagnosis or treatment. This admittedly is a very difficult line to draw, especially in the face of pressure from the patient, who wants to "get his money's worth" from his insurance. If any overuse does exist, each physician can assist in discouraging it by pointing out to the patient that each item of service enters into the cost to the subscriber.

Another area in which the individual physician can be of help to the Service is in the more accurate definition for the Claims Department of the pre-existing conditions that come under the exclusion clause in the contract, and in an explanation to the patient that such exclusions are necessary to prevent overloading the service with chronic conditions, and to prevent a subscriber from joining for

a brief period for the sole purpose of obtaining treatment for a known condition.

Particularly in view of the increase in premium rates, it behooves us as members of the New Hampshire Medical Society to remind ourselves of the conditions under which the New Hampshire Physician Service was constituted under the aegis of the Society. To avoid the complications of a service contract with an income limit for the subscriber, it was decided to get up the program on an indemnity basis, but at the same time to protect the low-income subscriber by mutually agreeing that in this subscriber group the fee charged should approximate the benefit listed in the schedule. The low-income group comprises roughly individual incomes up to \$2500 per year, and family incomes up to \$5500 per year. For such subscribers, therefore, the fee in the average case should not exceed the benefit allowed.

In the national field, an important development has been the appointment of Dr Paul R. Hawley, formerly of the Veterans Administration, as chief executive officer of the Blue Shield and Blue Cross National Organizations. A joint session of the Blue Shield and Blue Cross representatives was held this spring to discuss plans for the formation of a National Blue Cross-Blue Shield Association to co-ordinate the activities of the various local plans. Final action has not been taken on this proposal.

The American Medical Association has taken the incomprehensible action of cancelling its Blue Cross coverage for its employees and placing its insurance with a commercial carrier. Your committee considers this action a betrayal of the nonprofit plans set up under medical-society sponsorship, and therefore recommends the adoption of the following resolution.

Whereas, the American Medical Association has urged its component Medical Societies to establish nonprofit Medical insurance programs as the doctor's answer to the problem of distribution of medical care, and

Whereas, the American Medical Association has cancelled its Blue Cross coverage of its employees in favor of a commercial carrier, and

Whereas, this action represents a betrayal of the principle of nonprofit voluntary sickness insurance, which is the foundation of the medical-care plans sponsored by the component societies, therefore be it

*Resolved* that the New Hampshire Medical Society strongly disapproves of the action of the American Medical Association in cancelling its Blue Cross coverage and urges that the contract with Blue Cross be renewed.

The Committee is firmly convinced that the Blue Shield program is performing a valuable service both for the patient and for the physician and therefore continues to merit the full support of the members of the New Hampshire Medical Society.

Dr Sycamore moved that the Committee on Medical Economics be instructed to continue its negotiations with the State Board of Public Welfare regarding the welfare fee schedule.

The motion was duly seconded, and was carried with one dissenting vote.

Dr Sycamore then moved that the House of Delegates recommend to the members of the New Hampshire Medical Society that their full support be given to the New Hampshire-Vermont Physician Service.

This motion was duly seconded and was carried.

Dr Sycamore further moved that the proposed resolution regarding the American Medical Association and Blue Cross be adopted and that the Secretary be instructed to forward a copy to the Secretary of the American Medical Association.

Dr Sullivan asked why the American Medical Association had changed the procedure.

Dr Sycamore replied that a commercial company had offered to give the American Medical Association a guaranteed premium rate for the year, and the Blue Cross could not. The commercial company was offering indemnity contracts, and, of course, could guarantee the rates. Blue Cross was offering service contracts, and its costs might go up as hospital costs went up. The point at issue was that the American Medical Association had been fostering these nonprofit plans and had been requesting the local state and county societies to set them up and that, in taking the action discussed, had allied itself with the competitors of Blue Cross, in effect, it is saying that the commercial plans are more desirable.

Dr Friberg seconded Dr Sycamore's motion.

The Speaker then asked all those in favor of the motion to signify assent by saying "aye."

There was a chorus of "ayes" and some dissenting votes, but the motion was carried.

The report of the Committee on Mental Hygiene was then presented, as follows:

The New Hampshire Mental Hygiene and Child Guidance Clinics have been partly reorganized, and a full program is looked for in 1949. This program includes not only the diagnostic traveling activities but also the establishment of a program of psychiatric and psychologic care in a residential setting for children who need it—that is, for children who are emotionally disturbed, suffering from neuroses and with behavior and character disorders.

Since July, 1947, two psychologists, a psychiatric social worker and a senior clerk-stenographer have been added to the Mental Hygiene Clinic Staff, making a total personnel of nine.

Two new monthly clinics have been established, one in Portsmouth at the General Hospital, being sponsored by the Portsmouth Visiting Nursing Association and the Portsmouth Hospital. The second is in Keene at the headquarters of the Department of Public Welfare. These are in addition to the regular clinics held monthly in Concord, Manchester, Nashua, Laconia and Rochester, and also the three clinics of two days' duration held in Berlin, with plans to hold several clinics in the northern part of the State this summer.

The educational program in mental hygiene has been doubled this year. The director, Dr Anna Philbrook, has given thirty-seven talks to groups of nurses and teachers, parent-teachers groups and mothers' clubs and at present is teaching a course in mental hygiene to the Winnepesaukee Teachers Association. The course is attended by fifty-eight teachers, and consists of two-hour lectures given each week on Monday.

The Clinic psychologists are writing a mental-hygiene column for the newspaper, called "Know Yourself."

More treatment has been done by the individual members of the Clinic staff, particularly play therapy with children who are emotionally disturbed. Finger painting and play therapy carried out with the doll house and doll family have proved to be very useful this year, and more has been done than ever before.

Through the Veterans Administration, clinics for veterans with emotional disturbances are being conducted regularly by Dr Everett F. Lombard as director, who formerly was a member of the New Hampshire State Hospital Staff and a volunteer worker in the Mental Hygiene Clinic.

With the opening of the Children's Center in Concord and the addition of another psychiatrist to the Mental Hygiene Clinic Staff, there is a definite plan that should provide adequate service to the State.

The State Hospital is now planning also to open mental clinics in Manchester, Nashua, Dover, Rochester and Portsmouth, to which patients out on convalescent leave

may come to review their condition and progress. These clinics will be held monthly and will be attended by one of the physicians of the staff at the Hospital, a social worker, a psychologist and one clerical worker. It is hoped that the reopening of these clinics will give indigent adult patients suffering from emotional disturbances, neuroses or borderline mental illnesses an opportunity to attend the clinics for advice and outpatient treatment.

The State Department of Health, in co-operation with the State Hospital and the State Mental Hygiene Clinics, has recently opened a clinic for diagnosis and treatment of indigent patients with convulsive seizures. Facilities for electroencephalographic studies are now available at the New Hampshire State Hospital if so indicated. A clinician and a physician of the Hospital Staff are already trained respectively to take and interpret the readings. These facilities are also available for use in determining organic neurologic conditions of the brain, such as tumors for patients both within and without the Hospital.

In conjunction with the setting up of these clinics for convulsive seizures, it might be well to recommend a State survey of epileptics, which might include also a survey of backward children in the schools, with the view in mind of testing them by a psychologist for their I. Q., which would prove of value to their respective teachers.

The recent advances in treatment in neuropsychiatry by means of electroshock and insulin therapy and narcotherapy have aided materially in shortening hospitalization time of certain types of psychiatric patients, more noticeably depressive types and catatonic types of schizophrenia. The members of the Committee believe that if better facilities were available in general hospitals, a number of patients might be treated by these methods and thus prevented the necessity of entering a psychiatric or mental hospital for treatment there. It is thus recommended that in every newly built hospital, or where addition to a hospital is being contemplated, several beds, or preferably a small section, be set apart for the type of treatment mentioned above, in the belief that the patient probably would respond rapidly and favorably to it.

The problem of the care of feeble-minded children under the age of five, especially those afflicted with severe organic cerebral disorders, has come to the fore in view of the inability of the State School in Laconia to care for such patients. Individual county hospitals should be made to assume such responsibility as a last resort, or a more scientific medical approach to the problem would be for the State to build a special pavilion at the Laconia State School for such cases. The addition of the residential home in Concord for the intramural psychiatric study of certain psychiatric problems in children with normal intelligence will not alleviate in any way the need for special facilities for the care of the above group of cases.

The Committee recommends that a more intensive use of the sterilization laws might be of value in rehabilitation of certain cases of mentally ill and mentally defective persons to the point where they might be paroled from the institutions where they are now under treatment to proper environmental situations with suitable follow-up work by social agencies, because every available agency or interested person should be approached in any state hygiene program that may be instigated.

The State has come to recognize the chronic inebriate as a mentally sick person and now has a board that considers the problems from all angles. It hopes eventually to have proper facilities to care for the inebriate, staffed by a psychiatrist who would be a medical director, a psychologist and a clerical force and the proper amount of personnel. However, it seems to this Committee that the board should include as one of its members a psychiatrist, as well as the physician now on the board, who views the individual inebriate from a physiologic standpoint.

Shortly, it appears, from rising public interest, particularly in the courts, that the State must approach the problem of persons termed psychopaths more from a medical angle than ever before, and this should call for the appointment of a committee, which might emanate from the Governor and Council, to study this problem thoroughly and to render suggestions.

In conclusion, the members of the Mental Hygiene Committee feel that they, as well as the State in general, have met with a severe loss in the death of Dr. Charles H. Dol-

loft. He served as chairman of the Committee for many years. As a result of his interest and efforts, New Hampshire is in the vanguard in the institutional care of psychotic patients. He was also instrumental in organizing the State system of Mental Hygiene Clinics.

ARTHUR B. HOWARD, *Chairman*  
EDWARD S. MORRIS  
SIMON STONE

Dr. Sycamore moved that a copy of the paragraph in the report regarding facilities in general hospitals be sent to the president of the New Hamp-

shire Hospital Association, with the request that it be read at the next meeting of that association.

This motion was duly seconded and was carried.

Dr. Sycamore, for the Committee on Officers' Reports, also moved that the House of Delegates express its approval of a state survey of epileptic and psychopathic persons.

This motion was duly seconded and was carried.

(To be continued)

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

### Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

BENJAMIN CASTLEMAN, M.D., *Associate Editor*

EDITH E. PARRIS, *Assistant Editor*

### CASE 34401

#### PRESENTATION OF CASE

A forty-four-year-old woman was admitted to the hospital because of a tumor in the right side of the abdomen.

One month before entry the patient first experienced a dull pain in the right upper quadrant of the abdomen, which on the first day radiated to the umbilicus and the right costovertebral angle. There was no nausea, vomiting, anorexia, weight loss, change in bowel habits or urinary symptom accompanying the pain. After three days without relief the patient saw a physician and was subsequently admitted to another hospital. Barium studies and a Graham test were said to show a mass in the region of the right kidney extrinsic to the gall bladder and bowel. She was discharged from the hospital feeling well except for marked anxiety, depression and nervousness, these complaints being relieved by sedation. She had lost 10 pounds while on a restricted-calorie diet at home.

The patient had apparently always been well, there being no history of serious illness or previous operations. She had two deliveries, seven and five years before entry, without difficulty.

Physical examination disclosed a well developed, well nourished woman in no acute distress. The positive physical findings were limited to the abdomen where there was a smooth, firm mass below the right kidney and adjacent to the vertebral column. There was no costovertebral-angle or abdominal tenderness. Neither the spleen nor the liver edge could be felt and the contour of the

abdomen was normal. There was a question whether or not the right kidney could be felt.

The temperature, pulse and respirations were normal. The blood pressure was 110 systolic, 70 diastolic.

The blood hemoglobin was 13.8 gm, the white-cell count 7000, the prothrombin time 18 seconds (control, 16 seconds), the nonprotein nitrogen 22

FIGURE 1 Plain Film of the Abdomen, Showing a Lobular Mass in the Right Upper Quadrant. Arrow points to the straight line mentioned in the discussion.

mg and the total protein 6.4 gm per 100 cc. The urinary sediment showed a rare red cell, an occasional white cell and 30 epithelial cells per high-power field. The specific gravity was 1.020.

An intravenous pyelogram disclosed the presence of an ovoid mass of homogeneous density, showing a smooth, only slightly undulating margin situated in the right upper abdomen (Fig. 1). Its upper portion did not appear to be entirely included in the

films obtained. The mass measured at least 15 by 10 cm. Pyelography showed good kidney function and no evidence of intrinsic involvement of the urinary tracts or kidneys. However, the right kidney was displaced upward, its lower pole also being displaced medially, and the kidney being rotated on its vertical axis so that the ureter entered the renal pelvis more laterally than usual. The spleen may have been very slightly increased in size. There was no evidence of ureteral obstruction, and the bladder appeared normal.

On the fourth hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR LAURENCE L. ROBBINS. I assume that you do not have the x-ray films taken at the other hospital?

DR BENJAMIN CASTLEMAN. No.

DR ROBBINS. In summary, we have a forty-four-year-old woman whose complaint was pain in the right upper quadrant of one month's duration and the presence of a mass. That is just about as far as I am going to get in this discussion. First of all, it would be a tremendous help to know the relation of this mass to the gall bladder because one consideration would certainly have to be a hydrops of the gall bladder. It is not unusual to see a hydrops of the gall bladder in extreme cases do just what happened here. We must assume that the gall bladder was filled on the other examinations. What we see here is that the right kidney has been pushed upward and the lower pole rotated medially by a mass, the upper limits of which we cannot definitely define. Certainly, the greater portion of the mass is apparent, with suggestive lobulation at its inferior border and definitely something abnormal below and lateral to what we define as the edge of the lobular mass. We do see the kidney outline in its entirety so it would be unlikely that this arose from the kidney itself, unless we assume it arose from the anterior surface or posteriorly and worked around on a long, thin pedicle. These areas of calcification appear to be outside the mass and are probably nodes within the abdomen. The only abnormality in the intravenous pyelogram is the deformity of the inferior calyx, which can occur from extrinsic pressure.

Of the various things that we have to consider, I suppose one has to think of a dermoid cyst, which occasionally occurs in this area. If this was a dermoid cyst, it did not have the characteristic x-ray findings, such as the density of fat and areas of calcification within it.

So far as an inflammatory process such as tuberculosis is concerned, one has to think about the possibility that something extended downward from the region of the thoracic spine. But we have nothing to go on regarding that. This could have been an echinococcus cyst of the liver, but again,

we have nothing characteristic by x-ray examination. We would like a few flecks of calcification and something in the history to suggest it.

Of the various tumors in this region, a tumor of the adrenal gland is unlikely. I have already said I do not believe that it arose from the kidney. It is unlikely to be a primary tumor of the gall bladder in the absence of stones. However, we are assuming again that the Graham test previously noted was normal. Of the tumors of the liver, I do not believe it would be likely to be carcinoma because we have nothing to suggest it in either the history or the x-ray findings. There was questionable slight enlargement of the spleen, but it is unlikely to have been significant. A fair portion of the spleen could be seen, and it was not particularly enlarged. Hemangioma of the liver with hemorrhage intrigues me no end for two reasons: the apparent mass and the suggestion of some edema in the flank, which might possibly be the result of hemorrhage.

Another thing that is of some interest to me—nothing very definite—is that although the colon is displaced downward somewhat by this mass, one has the impression that the greatest pressure is on the proximal transverse colon and still we see something abnormal producing the straight line just above the iliac crest (Fig. 1), which I cannot explain unless it is due to hemorrhage or edema, which is possibly pushing the attachment of the ascending colon and hepatic flexure inferiorly. One other thing that goes along with the possibility of hemorrhage is the loss of the preperitoneal fat line. That is also present with edema or inflammation. From the clinical findings we have nothing to suggest an inflammatory process.

Can it possibly have been a lymphoma? It might have been, but I have never seen one with this appearance.

We come now to a group that is not too uncommon, the retroperitoneal connective-tissue tumors, and certainly they have to be given major consideration. The bulk of the mass, however, as we see it in these films, protrudes into the abdomen. There is preservation of the psoas outline and of the kidney outline, which is slightly against a typical retroperitoneal tumor.

I said at the beginning that I was going to come to the conclusion that there was a mass. I feel quite elated that I can see the mass because in many cases of abdominal masses it is not possible to demonstrate them on the films. I frankly cannot make a definite diagnosis, and I certainly think that surgery was indicated to determine the nature of the lesion.

DR CASTLEMAN. Do you not want to give us your first hunch?

DR ROBBINS. My first hunch would have to be what I ended with—a retroperitoneal connective-tissue tumor. The other possibility, heman-

gioma of the liver is not very good statistically

DR CASTLEMAN Dr Miller, will you tell us what Dr Sweet thought about this before operation?

DR CARROLL C MILLER Dr Richard H Sweet approached the case with an open mind. He had no definite idea what the mass was, but it was generally believed that it was probably in the liver because it was so very easily palpable beneath the anterior abdominal wall. We were not aware of any external edema in the flank tissues on palpation. There was no tenderness in this area. It did not seem to us to be an inflammatory process. The operation was done purely on the basis of making a diagnosis and treating the condition if that were possible.

#### CLINICAL DIAGNOSIS

Tumor of liver.

#### DR ROBBINS'S DIAGNOSIS

Retroperitoneal connective-tissue tumor?  
Hemangioma of liver?

#### ANATOMICAL DIAGNOSIS

*Congenital cyst of liver*

#### PATHOLOGICAL DISCUSSION

DR MILLER When the abdomen was first opened the mass presented itself readily. For a few minutes it was difficult to tell what the mass was. It was obviously a cystic tumor, and Dr Sweet thought this might be an enlarged hydroptic gall bladder because he could not find the gall bladder. After a bit more dissection all around the mass he found that the gall bladder lay medially, the tip of it being in normal apposition to the liver. The tumor was attached to the undersurface of the liver and protruded in the same way a hydroptic gall bladder would, except that it was a little more lateral to it. There was a very distended capsule over the cyst. With rapid dissection the capsule was stripped off the cystic mass, and the mass was easily removed. We were not able to get a clear idea of the tissue surrounding this area. In other words, we could not corroborate Dr Robbins's guess that there may have been edema. If there was, it was retroperitoneal, running out laterally in the flank. I do not believe much of any edema was present—certainly, no hemorrhage. The denuded area on the undersurface of the liver was closed easily, as one would close a gall-bladder bed. The abdomen was drained.

DR ROBBINS May I add one thing? I intended to include the possibility of lymphangioma of the liver and also meant to say that by x-ray the mass apparently was not so firm as it seemed clinically because there was a definite change in the shape of this lesion on some of the films. It was one reason why I thought of hemangioma of the liver as a very definite possibility.

DR CASTLEMAN The cyst that we received was multilocular, made up of four or five daughter cysts, the largest one about 6 cm in diameter. The entire mass was 13 by 7 by 8 cm. It was well encapsulated and filled with a clear straw-colored fluid, with no hemorrhage in it, and no evidence of infection—at least, no recent infection. The wall in several places was thickened, in most places it was rather thin. On microscopical examination a definite epithelium was found, very similar to the epithelium of the bile duct, and I therefore feel quite certain that this was a cyst of liver origin and probably arose from the bile ducts.

There are several theories regarding the etiology of cysts of the liver—that is, the nonparasitic cysts, most of which are on a congenital basis. The cysts arise from the bile-duct epithelium owing either to intrahepatic obstruction or, according to Moschowitz,\* to obstruction in a congenitally aberrant extrahepatic bile duct. One reason for believing the latter is that most of these cysts of the liver extend out from the liver on its inferior surface, protruding out just like a hydroptic of the gall bladder, suggesting that it was an extrahepatic rather than an intrahepatic bile duct that occurred congenitally in an aberrant fashion, which was blocked to produce the cyst. I think that was true in this case. Dr Robbins's second choice of hemangioma of the liver was pretty close, I do not recall ever seeing a hemangioma of the liver this large.

DR ROBBINS I understand from the literature that they can occur this large. One would have liked to find a phlebolith to confirm the diagnosis of hemangioma, although they do not always occur. They do tend to grow with increasing age.

DR CASTLEMAN The angiomas that we see at autopsy are usually small.

The other type of cyst that one occasionally sees in the liver is that associated with polycystic kidneys. They are usually much smaller and multiple, I do not believe there was any evidence in this case of polycystic kidney disease.

DR ROBBINS No, I did not consider a cyst of the liver because there were no changes in the films that suggested polycystic disease of the kidneys.

### CASE 34402

#### PRESENTATION OF CASE

*First admission* A nineteen-year-old unmarried secretary entered the hospital complaining of jaundice of four months' duration.

Seven months before admission she was in bed for a week with a "streptococcal throat" and a maximum temperature of 103°F, which cleared up without chemotherapy. One month later she had a tooth extracted, followed by considerable

\*Moschowitz, E. Non parasitic cysts (congenital) of liver with and without aberrant bile duct. *J. M. Sc.* 131:644, 1906.

bleeding Five months before admission she had "trench mouth," with tender, bleeding gums It responded initially to sodium perborate but later recurred At about the same time she noted the onset of painless jaundice Her physician advised a "fat-free" diet She continued to work, and the jaundice continued Two months before admission the jaundice became marked for about a week, and a transient swelling of the ankles followed She gained 15 pounds during the two months before admission She had noticed dark urine and light stools For about four months she had epistaxis about once each week

There was no nausea, vomiting, abdominal pain, melena or previous jaundice There was no history of exposure to sulfonamides, arsenic or solvents Before the onset of jaundice her alcohol intake was limited to an occasional cocktail The menses stopped two months before admission

Physical examination showed the patient to be slightly overweight, and the scleras were slightly icteric The head, neck, shoulders and arms were covered by a fine maculopapular, erythematous, dry, scaling rash The teeth were carious, and the gums infected and raw A systolic murmur was present at the apex and in the pulmonic area A systolic thrill was palpable at the third interspace The abdomen was tense On deep inspiration the liver was tender, and the edge was felt two finger-breadths below the costal margin Most observers felt the spleen on deep inspiration There was minimal ankle edema

The temperature was 98.6°F, the pulse 72, and the respirations 20 The blood pressure was 130 systolic, 70 diastolic

Examination of the blood disclosed a white-cell count of 7100, on one examination the differential was 70 per cent neutrophils, 17 per cent lymphocytes, 3 per cent monocytes, 8 per cent eosinophils, 1 per cent basophils and 1 per cent myelocytes The hemoglobin ranged between 13.5 and 8.8 gm The urine was amber colored, with a specific gravity of 1.020 Urobilinogen was present, varying from 1.280 to 1.24 on different examinations Bile was present, sugar, albumin and Bence-Jones protein were not observed The stools were tan and guaiac negative A blood Hinton test was negative The serum bilirubin was 3.65 mg per 100 cc direct, 5.85 mg total The phosphorus was 5.0 mg, the nonprotein nitrogen 18 mg, the serum albumin

2.0 gm, and the serum globulin 7.8 gm per 100 cc The alkaline phosphatase was 50 units The cephalin-flocculation test was ++++ in twenty-four hours Serum vitamin A and carotenoids were 0 units per cubic centimeter The prothrombin time ranged between 36 and 42 seconds (control, 15 seconds) The bromsulfalein test demonstrated 55 per cent retention of the dye in the serum The cholesterol was 123 mg, and the esters 46 mg per 100 cc X-ray examination of the chest and a gastrointestinal series were negative except for a small hiatus hernia

The patient was hospitalized for three months, was afebrile and was maintained on a high-carbohydrate, high-protein and low-fat diet supplemented by methionine, hykinone, components of the vitamin B complex and liver extract She received repeated blood transfusions Toward the latter part of the course all her teeth were removed because of abscesses and severe caries At the time of discharge the clinical and laboratory status had not altered markedly from the findings on admission The prothrombin time was 29 seconds (control, 19 seconds), the serum van den Bergh 2.1 mg per 100 cc direct, 2.9 mg indirect, the cephalin-flocculation test ++++ in twenty-four hours, the serum albumin 2.06 and the globulin 9.94 gm per 100 cc, and the nonprotein nitrogen 21 mg per 100 cc The vitamin A was 1.4 units and the carotenoid 0.8 units per cubic centimeter

*Second admission* (fifteen months later) During the interval the patient was followed carefully and maintained on a high-calorie, high-protein, low-fat diet, with supplementary vitamins Her activities were limited She felt better, and the jaundice was minimal There was no ascites or edema The laboratory data did not change remarkably One week before admission a mild cold began, followed in a day by moderate amounts of green sputum, chilly sensations and temperature rises up to 103°F Five days before admission the ears became tender, and a purulent, bloody exudate appeared Three days later she had a severe, sharp pain in the right chest on deep inspiration

Physical examination showed a moderately obese and pale woman, who complained of severe pain in the right chest with respiration Spider angiomas were present on the dorsal surfaces of the hand and neck The scleras were muddy There was marked conduction deafness, and the eardrums were red

and beefy, with landmarks obscured. There were dullness and diminished breath sounds at the right base, and bronchial breathing over the right middle lobe. An inspiratory friction rub was heard over the right lower lobe. Examination of the abdomen was unsatisfactory because of limitation of breathing. There was no ascites, but there was very slight pitting edema over the ankles.

The temperature was 99°F, the pulse 100 and the respirations 32. The blood pressure was 135 systolic, 70 diastolic.

Examination of the blood disclosed a red-cell count of 2,300,000 with a hemoglobin of 8.9 gm, and a white-cell count of 13,800 with 86 per cent neutrophils. The urine was amber and gave a + test for albumin and a +++ test for bile. Blood and throat cultures were negative. The serum albumin was 1.83 gm and the globulin 8.68 gm per 100 cc. The van den Bergh reaction was 2.2 mg per 100 cc direct, 2.9 mg indirect. The cholesterol was 89 mg, the cholesterol esters 31 mg, and the alkaline phosphatase 10 units per 100 cc. An esophagram demonstrated no varices.

On penicillin therapy the local signs and symptoms in the ears and right chest slowly subsided. The patient was discharged after three weeks of hospitalization.

*Final admission* (fifteen months later). One month before admission stiffness and pain in the knee joints, shoulders and the proximal interphalangeal joints of the right hand developed. Aspirin relieved the joint symptoms readily. Aside from joint pain the patient was asymptomatic. There was no ascites, but slight edema developed toward the end of the day. About three weeks before admission she fell and cut her right knee, but it healed promptly. Eight days before admission she awoke with a tender right calf and groin. The leg became swollen below the knee, and "blood blisters" appeared on the ankle, sole, left elbow and coccyx. She became restless, and the temperature became elevated. She lost her appetite, the abdomen became distended.

Physical examination showed the patient to be mildly icteric. A few scattered spider angiomas were present. There were coarse inspiratory rales at both bases posteriorly. The heart was not enlarged. The pulmonic second sound was louder than the aortic. Grade II pulmonic systolic and apical systolic murmurs were present. The abdomen

was distended, and a fluid wave was elicited. The liver edge was percussed two fingerbreadths below the costal margin. Peristalsis was active. The right leg was tense, swollen, tender and reddened below the knee. There was marked calf tenderness but no thigh or groin tenderness. The foot was swollen and tender, with several superficial erosions on the sole.

The temperature was 99.5°F, and the pulse 84.

Examination of the blood disclosed a white-cell count of 18,300, with 81 per cent neutrophils, and a hemoglobin of 10.5 gm. The urine contained bile. The stools were guaiac negative. The serum albumin was 1.65 gm, the globulin 6.80 gm, the cholesterol 109 mg, the nonprotein nitrogen 21 mg, the fasting blood sugar 90 mg, the calcium 8 mg, the phosphorus 3 mg per 100 cc, and the sodium 129 milliequiv and the chloride 100 milliequiv per liter. The alkaline phosphatase was 6.2 units per 100 cc. The van den Bergh reaction was 1.4 mg per 100 cc direct, 1.9 mg indirect. The prothrombin time was 26 seconds (control, 16 seconds). The cephalin-flocculation test was +++ in twenty-four and forty-eight hours.

X-ray examination of the chest demonstrated elevation of both leaves of the diaphragm. In the abdomen there was considerable fluid, there were gas-filled loops of small bowel but no definite evidence of organic obstruction.

On the third hospital day an abdominal paracentesis yielded 8500 cc of light-yellow, cloudy fluid, with a specific gravity of 1.008. Two days later the patient suddenly noticed steady upper abdominal pain, with some radiation to the back, relieved only partially by codein and demerol. On the following day she became nauseated and vomited bright-red-blood-stained material. The vomiting of blood continued intermittently. Seven transfusions were given over several days. The white-cell count reached 21,800, with 84 per cent neutrophils. The blood pressure ranged from 70 systolic, 40 diastolic, to 110 systolic, 60 diastolic. The pulse was rapid.

On the sixth hospital day, after thirty-six hours of coma, deepening jaundice and pulmonary congestion, the patient died.

#### DIFFERENTIAL DIAGNOSIS

DR. MARIA N. ROPES. I cannot make a diagnosis in this case but probably the most profitable way

bleeding Five months before admission she had "trench mouth," with tender, bleeding gums It responded initially to sodium perborate but later recurred At about the same time she noted the onset of painless jaundice Her physician advised a "fat-free" diet She continued to work, and the jaundice continued Two months before admission the jaundice became marked for about a week, and a transient swelling of the ankles followed She gained 15 pounds during the two months before admission She had noticed dark urine and light stools For about four months she had epistaxis about once each week

There was no nausea, vomiting, abdominal pain, melena or previous jaundice There was no history of exposure to sulfonamides, arsenic or solvents Before the onset of jaundice her alcohol intake was limited to an occasional cocktail The menses stopped two months before admission

Physical examination showed the patient to be slightly overweight, and the scleras were slightly icteric The head, neck, shoulders and arms were covered by a fine maculopapular, erythematous, dry, scaling rash The teeth were carious, and the gums infected and raw A systolic murmur was present at the apex and in the pulmonic area A systolic thrill was palpable at the third interspace The abdomen was tense On deep inspiration the liver was tender, and the edge was felt two finger-breadths below the costal margin Most observers felt the spleen on deep inspiration There was minimal ankle edema

The temperature was 98.6°F, the pulse 72, and the respirations 20 The blood pressure was 130 systolic, 70 diastolic

Examination of the blood disclosed a white-cell count of 7100, on one examination the differential was 70 per cent neutrophils, 17 per cent lymphocytes, 3 per cent monocytes, 8 per cent eosinophils, 1 per cent basophils and 1 per cent myelocytes The hemoglobin ranged between 13.5 and 8.8 gm The urine was amber colored, with a specific gravity of 1.020 Urobilinogen was present, varying from 1.280 to 1.24 on different examinations Bile was present, sugar, albumin and Bence-Jones protein were not observed The stools were tan and guaiac negative A blood Hinton test was negative The serum bilirubin was 3.65 mg per 100 cc direct, 5.85 mg total The phosphorus was 5.0 mg, the nonprotein nitrogen 18 mg, the serum albumin

2.0 gm, and the serum globulin 7.8 gm per 100 cc The alkaline phosphatase was 50 units The cephalin-flocculation test was ++++ in twenty-four hours Serum vitamin A and carotenoids were 0 units per cubic centimeter The prothrombin time ranged between 36 and 42 seconds (control, 15 seconds) The bromsulfalein test demonstrated 55 per cent retention of the dye in the serum The cholesterol was 123 mg, and the esters 46 mg per 100 cc X-ray examination of the chest and a gastrointestinal series were negative except for a small hiatus hernia

The patient was hospitalized for three months, was afebrile and was maintained on a high-carbohydrate, high-protein and low-fat diet supplemented by methionine, hykinone, components of the vitamin B complex and liver extract She received repeated blood transfusions Toward the latter part of the course all her teeth were removed because of abscesses and severe caries At the time of discharge the clinical and laboratory status had not altered markedly from the findings on admission The prothrombin time was 29 seconds (control, 19 seconds), the serum van den Bergh 2.1 mg per 100 cc direct, 2.9 mg indirect, the cephalin-flocculation test ++++ in twenty-four hours, the serum albumin 2.06 and the globulin 9.94 gm per 100 cc, and the nonprotein nitrogen 21 mg per 100 cc The vitamin A was 1.4 units and the carotenoid 0.8 units per cubic centimeter

*Second admission* (fifteen months later) During the interval the patient was followed carefully and maintained on a high-calorie, high-protein, low-fat diet, with supplementary vitamins Her activities were limited She felt better, and the jaundice was minimal There was no ascites or edema The laboratory data did not change remarkably One week before admission a mild cold began, followed in a day by moderate amounts of green sputum, chilly sensations and temperature rises up to 103°F Five days before admission the ears became tender, and a purulent, bloody exudate appeared Three days later she had a severe, sharp pain in the right chest on deep inspiration

Physical examination showed a moderately obese and pale woman, who complained of severe pain in the right chest with respiration Spider angiomas were present on the dorsal surfaces of the hand and neck The scleras were muddy There was marked conduction deafness, and the eardrums were red

of pneumonia. The fluid is consistent with the generalized anasarca that the patient had at the time of the last admission.

The joint symptoms that occurred at the time of the third admission are again not consistent with an uncomplicated liver disease. Furthermore, the final episode, although probably associated with the underlying liver disease, does not sound as though it was related to bleeding varices, although this has to be considered. The degree of pain and the relatively slow bleeding even in the presence of a low prothrombin would be unusual in bleeding varices. The type of bleeding and pain suggests the possibility of slow perforation of the stomach. It seems less likely to have been associated with the underlying liver disease.

So I should think that the final problem is to determine whether the patient had merely primary liver disease with some associated complications or whether the liver disease was part of a generalized process. The fact that makes one wonder most about a generalized process is the high globulin. One would think immediately about granulomatous diseases or other diseases causing elevation of globulin, such as sarcoid, tuberculosis, syphilis and possibly brucellosis, they elevate globulin although rarely to this height. One does not need to consider too seriously a malignant neoplastic process such as lymphoma or myeloma as the cause of the entire picture. The course over three years would be unusual for such a diagnosis. Also, one does not need to consider the group of connective-tissue diseases, such as disseminated lupus erythematosus or periarteritis nodosa. Some of them, particularly rheumatoid arthritis, develop high globulin levels in this range. However, the rest of the picture offers nothing, or practically nothing, in support of these diseases. Similarly, amyloid disease, which one thinks of always in the presence of hyperglobulinemia, has little to support it other than that and the presence of liver involvement.

So I am left with no possible evidence for any of the types of conditions that come to mind as the cause of liver disease as part of a generalized process. To be sure the liver involvement, the eosinophilia, the arthralgia and the high globulin are consistent with sarcoid. However in the absence of the more characteristic or specific lesions of this disease, it seems unwise to make such a diagnosis. The only diagnosis that I can make is parenchymatous liver

disease progressing to a chronic state with the development of cirrhosis. Whether or not it was part of an underlying generalized disease such as sarcoid, I think there is no evidence to determine.

DR TRACY B MALLORY: Dr Ellis, will you tell us what you thought about this case?

DR DANIEL S ELLIS: There is no one here today who followed the patient throughout the entire illness, although she spent most of it in this hospital. I saw her on several occasions in the various clinics, Medical Grand Rounds and Gastrointestinal Rounds. We were puzzled by the same things that Dr Ropes has pointed out. There were many different opinions about the etiology of the disease. One possibility that Dr Ropes did not mention, suggested by one member of the staff, was that this patient had some vascular disturbance in the form of thrombosis in the major circulation in the liver to account for some of the picture. Then in the final episode I am told that she was admitted to the hospital with a diagnosis of thrombophlebitis. It was believed by some that this might tie in with what had gone on several years before. We were puzzled by the high globulin. Most of the people who saw her decided that she had hepatitis and treated her from that standpoint. On one occasion I suggested that here was a patient who had had arthritis, serositis (pleurisy), jaundice, dermatitis with eruption, fever and high globulin and wondered if she might not at some time have fitted in with the picture of disseminated lupus. The urinary findings did not fit the picture of disseminated lupus, however. I am sure that this patient had a disease that involved more of her organs than the liver. I thought the liver was a part of the picture but probably not primary. Whether or not Dr Mallory will be able to tell us the underlying disease I do not know, but I think we were right in treating her for hepatitis because that was the one thing we could focus on and that was the basis on which we moved throughout the three years of illness.

Two liver biopsies were taken when she was first seen and again on the second admission. Dr Mallory will tell about the biopsies in relation to what the final picture showed.

#### CLINICAL DIAGNOSES

Cholemia

Varices of esophagus, with hemorrhage

Toxic cirrhosis of unknown cause

Thrombosis of veins of left leg

to approach it is to consider the involvement of the various systems separately and then to see if they can be related. The most apparent involvement is that of the liver, which started three years before death and persisted until the time of death. The entire course during the first two and a half years can be explained, I think, by hepatitis going into a chronic state with the development of cirrhosis. Usually in liver disease there is a great deal of difficulty in using the laboratory findings to differentiate obstructive jaundice and parenchymatous involvement. In this case the laboratory tests were entirely consistent with parenchymatous liver disease. The ++++ cephalin-flocculation test, the prolongation of prothrombin time to 42 seconds with lack of response to vitamin K, the low carotenoids, the low vitamin A, the very low cholesterol, with extremely low percentage of esters, the urobilinogen varying in amounts but found in the urine and the high bromsulfalein retention are all entirely consistent with liver-cell disease. The serum bilirubin gave more of the direct than the indirect reaction, in the neighborhood of 60 per cent, but this is lower than that ordinarily found in obstructive jaundice. So the laboratory tests are more consistent than those in the majority of cases with parenchymatous disease. I neglected to say that the alkaline phosphatase at the first admission was also normal. There is, however, one laboratory finding that to me was very surprising: the high globulin. One expects with hepatitis or liver-cell damage to get a lowering of albumin and some elevation of globulin, with reversal of the ratio. An increase up to 8 or 10 gm. of globulin is surprising, however, and unusual in uncomplicated liver disease. The course following the first admission, as I said before, is consistent to my mind with liver-cell damage progressing into a chronic state and with the development of cirrhosis. This took some two and a half or three years to occur. However, there are a good many findings in the total picture that are not explained by such a diagnosis. In the first place, we have no definite evidence of the cause of this hepatitis. Of course, infectious hepatitis has to be considered, and there is nothing to rule it out. We know that this patient was not exposed to some of the causes of liver-cell damage, but we have no further information about other toxins or of the possible role various cosmetics played in damaging the liver. Furthermore, the presence of

the very high globulin raises the question of some other generalized condition as the cause of the liver damage.

Now to consider a few of the other systems involved in the course of the disease, I think the rash that was present at the first admission and, I judge, not present at other admissions, was not part of the picture of liver disease, but with no further information I cannot offer any explanation for it. At the time of the second admission the patient had, I judge, bilateral otitis media and what I am interpreting as pneumonia. Whether or not she had underlying pulmonary disease is significant, and I think we should see the x-ray films to determine whether there was any involvement of the hilar lymph nodes or evidence of pulmonary disease other than pneumonia at the time of the second admission.

DR JAMES J. McCORT: This examination of the chest was made at the time of the second admission. The film taken on the day of admission shows an area of increased density in the medial segment of the middle lobe, which has the appearance of pneumonia. There is no enlargement of the hilar lymph nodes and no other evidence of pneumonitis that I can see. The film taken one week later shows a slight resolution of the pneumonic process in the middle lobe. However, at that time there is a definite suggestion of fluid in the right base posteriorly. The film taken two weeks after admission shows the pneumonitis to have undergone almost complete resolution. There is still a small amount of fluid in the right base. The right leaf of the diaphragm is slightly higher than it should be in this examination, possibly owing to the pressure of the liver.

DR ROPES: Is the chest entirely clear except for elevation of the diaphragm on the last admission?

DR McCORT: No. There is a slight amount of fluid in the left pleural cavity. There is also basal atelectasis, which I believe is due to the high diaphragm. The lungs are otherwise clear, and there is no mediastinal adenopathy.

DR ROPES: The gastrointestinal series shows nothing but the hiatus hernia, which I assume was not related to the rest of the picture.

DR McCORT: The gastrointestinal series was done at the second admission.

DR ROPES: I judge we have no evidence of underlying pulmonary disease — only the one episode

## PRIZE ESSAY COMPETITION

In acknowledgment of the support of more than 4000 student subscribers, the *Journal* announces a prize essay contest open to all members of the class of 1949 registered in any medical school approved by the Council on Medical Education and Hospitals of the American Medical Association.

The subject chosen for this year's competition is "Recent Advances in Preventive Medicine."

Manuscripts are to be between four and five thousand words in length, clearly typewritten in English, double or triple spaced with references listed at the end in numerical arrangement according to the form used by the *Quarterly Cumulative Index Medicus*. They must be in the hands of the editor

by March 15, 1949. All manuscripts will become the property of the *Journal*.

A cash prize of \$100 will be paid for the best essay of those found to be suitable for consideration; the paper will be published in the "Medical Progress" series that forms a regular part of the contents of the *Journal* and the author will receive a hundred free reprints.

A second prize will consist of a two-year subscription to the *Journal*.

The editors wish to emphasize that in establishing this competition they are as much interested in encouraging good medical writing as they are in promoting the collection of scientific material. In judging papers that may be submitted, particular attention will accordingly be paid to clarity, simplicity and general literary excellence.

The quality of medical writing needs at present more encouragement than the quantity of its production does.

## CHILD SAFETY

IN CO-OPERATION with the United States Children's Bureau, the American Academy of Pediatrics and the National Safety Council, the Metropolitan Life Insurance Company has undertaken an intensive campaign to prevent accidents in children. A special packet of material, which is available on request for use in local organized programs, includes copies of recent statistical studies, prepared talks and suggested area releases, as well as a twelve-page illustrated booklet, *Help Your Child to Safety*, addressed to parents and emphasizing the value of co-operation among all members of the family to combat physical hazards and unsafe practices resulting in injuries to children.

As previously pointed out in these columns, accidents account for an unwarranted number of deaths among persons of all ages each year.<sup>1</sup> However, the situation among children is even more discouraging; accidents now rank as the leading cause of death, as well as an outstanding cause of injury and permanent disability among children from one to fifteen years of age. The prevention of this enormous toll offers a challenge to all agencies interested in the health and welfare of children. To encourage parents, other adults and older chil-

## DR ROPES'S DIAGNOSIS

Hepatitis, chronic, with cirrhosis

## ANATOMICAL DIAGNOSES

*Cirrhosis of liver, postatrophic type*

*Adenoma of liver*

*Esophageal varices, with rupture*

Cholelithiasis

Bronchopneumonia

Anasarca

## PATHOLOGICAL DISCUSSION

DR MALLORY I do not know that I can give a satisfactory answer to this case, although I can describe the somewhat unusual findings at autopsy. As Dr Ellis said, we had two biopsies, one within six months of the first symptom, and one approximately a year after that. At the very first biopsy cirrhosis of the liver was already established. It was apparently of the type that follows regeneration from a severe degree of atrophy, quite consistent with a primary infectious hepatitis, but I would not be at all dogmatic about it. The second biopsy a year later had changed slightly, and we were very interested in finding great numbers of plasma cells in the stroma on that occasion. Although present in the first biopsy, they had not been numerous enough to excite our notice, but by the second time the patient had a high globulin, and we naturally tended to correlate this with the great numbers of plasma cells present. When she died the liver was still enlarged, weighing nearly 1900 grams, which is quite unusual for the type of cirrhosis that follows a healed atrophy. On the other hand, the gross appearance of the liver was otherwise characteristic. It was coarsely nodular, many of the nodules ranging from 1 to 2 cm in diameter. These nodules were very irregularly distributed, and there were large masses of tissue in which no nodules were found. There was one single nodule very much larger than any others that measured 5 cm in diameter in the middle of the right lobe, the center of which was soft and gelatinous. We did not find much else in the rest

of the body that seemed of interest. There were some shallow mucosal erosions in the esophagus.

On microscopical examination we found enlarged veins in the submucosa, and one of these erosions seemed to be communicating with a dilated vein so that I am confident that the terminal hemorrhage was due to rupture of a varix.

The spleen was only slightly enlarged, weighing a little over 400 gm, but in view of the massive hemorrhage it may have shrunk considerably in the last hours of life. There was a terminal very extensive bronchopneumonia. The gall bladder contained numerous small stones, but none were found in the duct system. The terminal pain may have been biliary colic, but unexplained abdominal pain is not unusual in cirrhosis.

From the histologic point of view the liver was characteristic of the postatrophic type of cirrhosis with the single exception of the plasma cells, which were more numerous than they are in most such cases. The very large nodule appeared to be composed entirely of liver cells. We could find no traces of bile ducts or portal veins in it. It contained very large amounts of fat, with some fatty acids. This was such a very large nodule, and completely devoid of normal liver architecture, that one had to classify it as a tumor. I could see no evidence of malignancy, and I would call it an adenoma of the liver. The bone marrow showed very marked erythroblastic hyperplasia, with a great many immature cells of the red-cell series. A few but not many plasma cells were present. It would have been quite impossible to make a diagnosis of multiple myeloma on the basis of the post-mortem findings so that all we have is a rather unusual type of cirrhosis with a great many more plasma cells in the scarred areas than we commonly see. These may or may not have had something to do with the unusual chemical findings, especially the high globulinemia.

DR JAMES T HEYL Because of the prolonged prothrombin time I am curious to know whether or not there was a thrombophlebitis.

DR MALLORY Large areas of hemorrhagic extravasation were found in the calf muscles, but no thrombi were seen in the major veins.

## CHILD SAFETY

IN CO-OPERATION with the United States Children's Bureau, the American Academy of Pediatrics and the National Safety Council, the Metropolitan Life Insurance Company has undertaken an intensive campaign to prevent accidents in children. A special packet of material, which is available on request for use in local organized programs, includes copies of recent statistical studies, prepared talks and suggested area releases, as well as a twelve-page illustrated booklet, *Help Your Child to Safety*, addressed to parents and emphasizing the value of co-operation among all members of the family to combat physical hazards and unsafe practices resulting in injuries to children.

As previously pointed out in these columns, accidents account for an unwarranted number of deaths among persons of all ages each year.<sup>1</sup> However, the situation among children is even more discouraging: accidents now rank as the leading cause of death, as well as an outstanding cause of injury and permanent disability, among children from one to fifteen years of age. The prevention of this enormous toll offers a challenge to all agencies interested in the health and welfare of children. To encourage parents, other adults and older chil-

dren to recognize the hazards confronting younger children, to provide and maintain safe conditions in the home and at play and to help the child, by example and guidance, to develop safe practices, the field force of the Metropolitan Life Insurance Company will participate in the child-safety programs of more than three thousand communities.

Physicians, who occupy a position of unique importance in the community, are urged to engage wholeheartedly in this campaign to reduce the number of injuries and deaths suffered by children. The efforts of general practitioners (who see the major portion of preschool children<sup>2</sup>) and pediatricians will be of particular value.

### PENICILLIN IN SYPHILIS

A REPORT on the status of penicillin in the treatment of syphilis dated December 1, 1947 was recently published by the Syphilis Study Section of the National Institute of Health.\* It was estimated by the United States Public Health Service statisticians that at least 500,000 patients with syphilis in various stages have been treated with penicillin since the first report of its beneficial effects was made in 1943. A significant proportion of these cases form the basis of this report, the purpose of which is to summarize for the practicing physician the facts regarding penicillin in syphilis that are of clinical importance. The observations contained in this report should be of great practical help to all who are likely to be concerned with such therapy, and they should read this summary in detail. Only a few points are brought out here.

It is stated categorically that penicillin G, which is now available in crystalline form, is the most effective type in man. This is the final upshot of the intensive studies undertaken after irregular results had been encountered that proved to be due to the changing character of commercial penicillin. The poor results are traced to the appearance of increasing proportions of the less effective penicillin K, and this has not been corrected.

\*Status of penicillin in treatment of syphilis. *J A M A* 136 873 879 1948

As to the method of administration, the single intravenous injections are considered to be of little or no value because of the extremely rapid absorption and excretion cycle. The continuous intravenous drip, likewise, is of little practical value because of the necessity of continuous confinement of the patient to bed and the frequent occurrence of thrombophlebitis. Continuous intramuscular or subcutaneous administration has the same disadvantage, and, furthermore, it produces rather painful local reactions. The usual method employed and the one recommended is the use of intermittent intramuscular injections of aqueous solutions containing 50,000 to 100,000 units per cubic centimeter of either sterile water or isotonic sodium chloride solution. Intraventricular, intracisternal or intraspinal administration should be avoided both because of possible dangerous toxic reactions and because intramuscular therapy alone is effective in the treatment of neurosyphilis and no additional benefit is derived from the intrathecal route. The oral route likewise is not advised, but the use of prolonging agents, like penicillin in beeswax and peanut oil (and presumably the more recent procaine penicillin preparations), appears to offer a practical method that permits intramuscular injections to be given only once daily.

Of the toxic reactions the one that particularly concerns the treatment of syphilis is the Jarisch-Herxheimer reaction. This is encountered in about 50 per cent of patients with primary and secondary syphilis, but in such cases it is seldom if ever alarming and does not interfere with subsequent treatment. About 25 per cent of patients treated for latent or late syphilis experience a mild febrile reaction. Therapeutic shock, which may be serious and occasionally results in death, has been considered as possibly resulting from penicillin in occasional infants with congenital syphilis and in patients with cardiovascular syphilis or neurosyphilis. There is no indication that penicillin causes abortion in pregnant women.

There is little clear-cut evidence to indicate the existence of penicillin-resistant syphilis analogous to the familiar arsenic-resistant or bismuth-resistant syphilis or sulfonamide-resistant gonorrhea.

Attention is also called to the fact that when early syphilis and gonorrhea are acquired simultaneously penicillin given for the latter may delay or perhaps even suppress the lesions of syphilis. Patients treated for gonorrhea should therefore be followed over a period of at least four months with monthly serologic tests for syphilis. A sharp febrile reaction within the first twenty-four hours after the use of penicillin for gonorrhea should suggest concurrent early syphilis. If a diagnosis of syphilis is later established, the patient should be given a full course of treatment as indicated.

The results of penicillin alone seem satisfactory enough in early syphilis so that adjuvant therapy with arsenic or bismuth preparations or fever is not advised in the first course of treatment, but they may be used to advantage in patients in whom the original course of penicillin has failed. In dementia paralytica the use of fever or malaria to supplement the penicillin therapy may be expected to give better results than penicillin alone.

Details are given for the dosage and duration of penicillin treatment and the precautions to be taken for each of the various types of syphilis. This report may therefore serve as a useful guide to all physicians who undertake the treatment of this disease. Without doubt many of the details of the report, particularly those concerning dosage, will require modification as further experience accumulates. In the meantime, this is the most concise and authoritative summary available.

#### "PASSENGERS WILL PLEASE REFRAIN —"

THE *Journal of the American Medical Association*\* has made editorial comment on a potential health hazard that must have occurred as a possibility to many persons, without necessarily stimulating any number of them to a crusading pitch of activity. This hazard is the impartial distribution of toilet wastes along railroad lines — except, usually, in stations.

The practical difficulty of attaching a swiftly moving train to any permanent sewage system is obvious, the public-health implications, apparently, have been under consideration for a number of years. Recently the Joint Committee on Railway

Sanitation of the Association of American Railroads has tuned in on the problem and, in March and December, 1947, issued a technical and a supplementary report.

Research was carried out on the heavily traveled New York to Washington run of the Pennsylvania Railroad, and in the course of the investigation "the toilet habits of 2 000 persons were studied over a total of 6,201 passenger hours and 320,000 passenger miles." Since such a project of necessity covered a considerable area, in the interests of accuracy the wastes were collected in sealed containers carried underneath the cars.

Certain estimates were possible. Approximately 276,000 pounds (dry weight) of the material under discussion was spread per year along 226 miles of roadbed, or 0.694 pounds per linear yard. Found in the collection, although not included in the statistical analysis, were orange peelings, cigars and cigarette butts, cigarette packages, miniature whisky bottles, beer bottles, men's handkerchiefs and women's handbags.

Whether epidemic disease has actually resulted from this impartial and not inconsiderable contamination of roadbeds is problematical, certainly the possibilities are present. Perhaps the advice of the popular song, not originally intended for mixed company, should be reversed and passengers exhorted to use the station toilets and spare the rolling landscape.

#### MASSACHUSETTS MEDICAL SOCIETY COMMITTEE ON MEMBERSHIP

The following list of twenty-one names of members of the Massachusetts Medical Society, who are to be deprived of membership, together with their last known addresses, is published at the request of the Committee on Membership.

Any information concerning the correct addresses of these fellows will be appreciated by the secretary of the Society, 8 Fenway, Boston 15 Massachusetts.

Edward T. Abrahams (Berkshire), 511 North Street Pittsfield.

Victor Baer (Middlesex South), 276 Commonwealth Avenue, Boston.

Arthur J. Bischoff (Middlesex East), New England Sanitarium and Hospital Stoneham.

Chester E. Bromwell (Suffolk), 11 Gloucester Street Boston.

Martin F. Buell (nonresident), Dearborn Department of Health, Dearborn Michigan.

William B. Davidson (Worcester), 8 Howland Terrace, Worcester.

\*Current Comment. Railroad toilet wastes. *J A M A* 137 11:4 1948.

Winnifred P Davis (Worcester North), 79 Main Street, Ashburnham  
 David D Greene (Middlesex South), 117 Brackett Road, Newton

## MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### WEEKLY RATES FOR CARE OF PATIENTS IN DEPARTMENT HOSPITALS

Owing to greatly increased costs of hospital care during the past few years, it has been necessary to revise charges for the care of patients in institu-

This provided authorization for payment for patients expecting to be confined on or before April 4, 1948, as well as for retroactive cases—that is, cases in which the patient had been delivered between September 3, 1943, and April 4, 1948, even though the application was not submitted at the time care was given

However, in May, 1948, the Government ruled that no authorization for payment for maternity care could be issued after June 30, 1948

These limitations were publicized to the professional and lay public

Outstanding bills for care already authorized continue to come in covering payment for medical, hospital and ancillary services. More than 2000 cases are still incomplete. Letters and telephone calls for information or assistance are numerous and the depleted staff is kept busy

### Infant Cases

Care is still available for eligible infants born on or before April 4, 1948. The number of cases naturally is decreasing, but authorization for payment for care will continue to be issued to cover all illnesses, including medical, hospital and other care, such as immunizations, until these infants become one year of age (in April, 1949)

TABLE 1

INSTITUTION	TYPE OF DISEASE	AGE OF PATIENTS	TOTAL WEEKLY CHARGE	
			BY PATIENT	BY CITY OR TOWN
Rutland and Westfield (Tuberculosis Section) North Reading	Pulmonary tuberculosis	17 yr and over	\$14	\$14
	Pulmonary tuberculosis	Under 17 yr	\$14	\$14
	Rheumatic heart disease	Under 17 yr	\$14	\$14
Lakeville	Extrapulmonary tuberculosis	All ages	\$14	\$21*
	Poliomyelitis (convalescent)	All ages	\$35	\$21*
Pondville and Westfield (Cancer Section)†	Cancer	All ages	\$21	\$40

\*\$14 if patient is under 21 yr of age

†Outpatient clinic (regardless of who pays bill) no charge for examination and \$3 per visit for treatment.

tions of the Massachusetts Department of Public Health. Table 1 presents the list of rates, effective July 1, 1948, as revised under the provisions of Section 66, Chapter 111 of the General Laws, as amended by Chapter 630 of the Acts of 1947

### LIQUIDATION OF EMERGENCY MATERNAL AND INFANT CARE PROGRAM

The Emergency Maternal and Infant Care Program is gradually being liquidated in the following manner

#### Maternity Cases

In May, 1947, the federal Government notified the states that payment for maternity care was limited to wives of men in the four eligible pay grades who became pregnant prior to July 1, 1947

#### Volume of Cases and Expenditures

For the period from September 3, 1943 (when the program began in Massachusetts), until July 1, 1948, a total of 43,541 cases were authorized. Of these, 33,486 were maternity, and 10,055 were infant cases. This does not include numerous individual separate authorizations for ante-partum and post-partum complications and nonobstetric conditions in maternity cases or for additional illness of many infants cared for by the same physician, nor does it include authorizations for consultant, nursing and other services. Rejections totaled 4934 cases, chiefly for noneligibility

The amount of money spent in this period was \$4,082,883.65. This expenditure was for cases only covering payment for hospital, medical and ancillary care. Administration funds were not included in this amount.

## LUE CROSS-BLUE SHIELD

### LUE CROSS APPLICATIONS

Membership in Blue Cross will again be available to all members of the Massachusetts Medical Society not now enrolled, as of December 1, 1948

For membership to be effective on that date all applications must be filed with Blue Cross not later than November 1, 1948

Thereafter, while applications will be received at any time, enrollments will become effective each quarter on March 1, June 1, September 1 and December 1 To become effective on these dates, however, applications must be received thirty days in advance

Those who desire to join should communicate with John H McLaughlin, enrollment representative, 38 Chauncy Street, Boston 11

## CORRESPONDENCE

### ACTION ON SPECIALTY BOARDS

To the Editor As advance information to the members of the Society I would remind them that the Hampden District Medical Society endorsed a resolution that can be found in the spring issue of the *Hippocrat* and was sent to all councilors This resolution is perhaps poorly drawn and I have since found on page 886 of the *Journal of the American Medical Association* of July 3, 1948, a more comprehensive resolution passed unanimously by the New York Medical Society and brought up under new business at the meeting of the American Medical Association

In the House of Delegates of the American Medical Association this resolution was referred to a reference committee on miscellaneous business, which re-referred it to a special committee of the Board of Trustees—that on Medical Practice and Hospitals, headed by Dr E Hess of Erie, Pennsylvania Dr Hess will give a report of his committee at the St. Louis meeting on November 30, 1948

The New York Society has 15 per cent of the national membership, the Massachusetts Medical Society is sixth in size in the nation, and the problems of the New York Society are ours No mention of instructions by the Massachusetts Medical Society to its delegates to the American Medical Association—Drs Phippen, Sullivan, and Curley—have as yet been noted Inasmuch as the subject matter of this resolution is vitally important to orderly medical practice I am preparing a presentation for action in the matter at the meeting of the Council on October 6 I hope that the councilors will come to the meeting informed sufficiently to express an opinion on the subject of specialty boards

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender Books that appear to be of particular interest will be reviewed as space permits Additional information in regard to all listed books will be gladly furnished on request

*The Acute Bacterial Diseases Their diagnosis and treatment* By Harry F Dowling M D, clinical professor of medicine, George Washington University School of Medicine, and chief George Washington Medical Division Gallinger Municipal

Hospital With the collaboration of Lewis K Sweet M D chief medical officer in pediatrics and infectious diseases Gallinger Municipal Hospital, adjunct clinical professor of pediatrics, George Washington University School of Medicine and Georgetown University School of Medicine, and Harold L Hirsh, M D, assistant professor of medicine, Georgetown University School of Medicine, and director, Bacteriology and Immunology Laboratory, Georgetown University Hospital 8°, cloth, 465 pp, with 55 illustrations and 52 tables Philadelphia W B Saunders Company, 1948 \$6 50

This new book on infectious diseases is intended as a practical guide for the practicing physician and presents the up-to-date knowledge on these diseases The individual diseases are classified according to the etiologic agents Diseases that are clinically similar have been grouped together whenever possible The work is based principally upon more than 7000 cases observed at Gallinger Municipal Hospital The text is divided into four parts The first deals with diagnosis and treatment in general, including the current use of the sulfonamides, penicillin and streptomycin The second part describes the diseases caused by the cocci, the third those caused by the bacilli, and the fourth, those in which exotoxins are a major factor Only the acute forms of tuberculosis are discussed because they are the ones most likely to be confused with other acute bacterial infections and because the chronic forms are usually treated in institutions by specialists The text is well written, and the book well published The volume is recommended for all medical schools and to the general practitioner

*Biology of Disease* By Eli Moschowitz, M D, physician, Mt Sinai Hospital, New York City 4°, cloth, 221 pp New York Grunc and Stratton, 1948 \$4 50

This book may be characterized as a series of essays on the evolution of certain chronic diseases or conditions in which the biologic factors are not too obvious The author points out that many chronic conditions present a distinct evolutionary progression from a primitive stage to the final form He classifies diseases into two great divisions those in which there is a well established pathogenesis, and those that can be classified on a grouping of clinical phenomena The diseases and syndromes discussed include hypertension, arteriosclerosis, periarthritis nodosa, Libman-Sacks disease, polycythemia vera leukemia, follicular lymphoblastoma, myeloma, Graves's disease, toxic hepatitis, Laennec or portal cirrhosis, glomerulonephritis, obesity, peptic ulcer, achlorhydria in relation to anemia, cardiopasm, sprue syndrome, emphysema, uremia, nephrosis and the hyperkinetic diseases Also there is a chapter on psychosomatic medicine The essays are scholarly and well written A selected list of references is appended to each chapter A good index concludes the volume The publishing is excellent The book is recommended for all medical libraries and to all physicians interested in chronic forms of disease

*The 1947 Year Book of Endocrinology, Metabolism and Nutrition "Endocrinology"* Edited by Willard O Thompson, M D clinical professor of medicine, University of Illinois College of Medicine, attending physician (senior staff), Henry Hospital, and attending physician, Grant Hospital of Chicago "Metabolism and Nutrition" Edited by Tom D Spies, M D, chairman, Department of Nutrition and Metabolism Northwestern University School of Medicine, and director Nutrition Clinic, Hillman Hospital Birmingham, Alabama 12°, cloth, 575 pp, with 86 illustrations Chicago The Year Book Publishers, Incorporated, 1948 \$3 75

This second issue of a standard reference work covers the literature on its subjects for the period from November, 1946, to October, 1947 The literature on the pancreas has been transferred from "Endocrinology" to "Metabolism and Nutrition" The text comprises abstracts of original articles on various topics selected for their importance The citations to original sources are printed as footnotes on the appropriate pages Good indexes of subjects and authors conclude the volume The text is well printed with good type on coated paper The book is recommended as an essential reference work for all medical libraries and to all persons interested in the subjects covered

Dr Arturo Rosenblueth, director, Physiological Laboratory, National Institute of Cardiology, Mexico City, and Dr Norbert Wiener, professor of mathematics, Massachusetts Institute of Technology, will speak on "The Shape of the Spike Potential of Nerve"

## METROPOLITAN STATE HOSPITAL

The following change in the schedule of the course in Pediatric Neuropsychiatry (child psychiatry) of the Fourteenth Postgraduate Seminar in Neurology and Psychiatry at the Walter E Fernald State School, announced in the September 9 issue of the *Journal*, has been made: this course will be given on Tuesdays, October 26, and November 9, 1948, and on Mondays, November 22 and December 6, 1948, and from March 14 until May 9, 1949, every second week from 6 00 to 9 30 p m

## NEW ENGLAND DERMATOLOGICAL SOCIETY

A regular meeting of the New England Dermatological Society will be held in the Skin Out-Patient Department of the Massachusetts General Hospital, at 2 p m on Wednesday, October 20. The meeting is open to members and invited guests only

## NEW ENGLAND DIABETES ASSOCIATION

The fall meeting of the New England Diabetes Association will be held in the Cheever Amphitheater of the Boston City Hospital on Wednesday, October 20, at 8 00 p m

The speaker of the evening will be Dr George W Thorn, whose subject will be "Some Fundamental Endocrine Relations in Diabetes"

After the clinical program there will be an important business meeting of the Association to discuss future policies

NEW ENGLAND  
PEDIATRIC SOCIETY

The fall meeting of the New England Pediatric Society will be held in Boston on Wednesday, October 27, 1948

Dr Lawson Wilkins, of Johns Hopkins Hospital, will be the speaker

A detailed program will be announced at a later date

AMERICAN SOCIETY FOR THE STUDY OF  
ARTERIOSCLEROSIS

A scientific meeting of the American Society for the Study of Arteriosclerosis will be held at the Hotel Knickerbocker, Chicago, on October 31 and November 1

AMERICAN BOARD OF OBSTETRICS  
AND GYNECOLOGY, INC

The following changes in Board requirements and regulations were made at the annual meeting of the Board held in Washington, D C, May 16 to May 22: the ruling that applicants must receive adequate training in both obstetrics and gynecology has been defined as meaning a minimum of six months, full time, in the branch of either obstetrics or gynecology relegated to a minor role in a candidate's training and preference for practice, acceptable preceptorship, training is defined, the present regulation requiring at least six months of practice in the specialty following the completion of an acceptable training period has now been extended, effective December 31, 1949, to a requirement of two years' post-training practice limited to the specialty; specific requirements for approval of hospital services for residency training are outlined, and effective immediately there will be no further temporary approvals of hospital services for residency training—it is planned that all hospitals holding any type of residency-training approval will soon be either resurveyed or initially surveyed by the Council on Medical Education and Hospitals of the American Medical Association so that all future approvals, new and old, will be based entirely upon inspection following application. It is expected also that certain resurveys will result in withdrawal of present residency approval from institutions where the educational and training standards are not being maintained

## THE USE OF THE RICE DIET IN THE TREATMENT OF HYPERTENSION IN NONHOSPITALIZED PATIENTS\*

ANDREW W. CONTRATTO, M.D.,† AND MIRIAM B. ROGERS

BOSTON

THIS report covers the first six months of a study of a group of ambulatory or nonhospitalized patients with hypertension who were treated with the rice diet. With the work of Kempner<sup>1-4</sup> as a guide but unlike his series in which all but a few patients were initially confined to a hospital, our patients were not hospitalized. So far as possible, nothing was changed in the daily routine of the patient except the diet. If he was ambulatory and working, this activity was continued. Patients who, when first started on the regime, were inactive because of their illness, continued on this routine except for the diet until improvement, if it did occur, warranted a more strenuous life. Moreover,

Of the 55 patients with essential hypertension who were started on the diet, 18 were excluded from the study because of nonco-operation. Some of these failed to return for subsequent visits after having been advised to follow the diet. Others after a few days, expressed unwillingness to remain on the diet, and still others, who did not admit their dietary divergence, were excluded because their twenty-four-hour urinary chloride excretions

# BRIEF HISTORICAL NOTES ON MEAD'S CEREAL, PABLUM AND PABENA

---

**H**AND in hand with pediatric progress, the introduction of Mead's Cereal in 1930 marked a new concept in the function of cereals in the child's dietary. For 150 years before that, since the days of "pap" and "panada," there had been no noteworthy improvement in the nutritive quality of cereals for infant feeding. Cereals were fed principally for their carbohydrate content.

The formula of Mead's Cereal was designed to supplement the baby's diet in minerals and vitamins, especially iron and thiamine. How well it has succeeded in these functions may be seen from two examples:

(1) As little as one-sixth ounce of Mead's Cereal\* supplies over 50% of the iron and 20% of the thiamine minimum requirements of the 3-months-old infant. (2) One-half ounce of Mead's Cereal furnishes all of the iron and 60% of the thiamine minimum requirements of the 6-months-old baby.

That the medical profession has recognized the importance of this contribution is indicated by the fact that cereal is now routinely included in the infant's diet as early as the third or fourth month instead of at the sixth to

twelfth month as was the custom only a decade or two ago.

In 1933 Mead Johnson & Company went a step further, improving the Mead's Cereal mixture by a special process of cooking, which rendered it easily tolerated by the infant and at the same time did away with the need for prolonged cereal cooking in the home. The result is Pablum, an original product which offers all of the nutritional qualities of Mead's Cereal, plus the convenience of thorough scientific cooking.

During the last twelve years, these products have been used in a great deal of clinical investigation of various aspects of nutrition, which have been reported in the scientific literature.

Many physicians recognize the pioneer efforts on the part of Mead Johnson & Company by specifying Mead's Cereal and PABLUM—and also the new Pablum-like oatmeal cereal known as PABENA.

---

\*Pablum, the precooked form of Mead's Cereal, has practically the same composition: wheatmeal (farina), oatmeal, cornmeal, wheat embryo, beef bone, brewers yeast, alfalfa leaf, sodium chloride, and reduced iron.

(expressed as sodium chloride) were so high as to make it obvious that they were not adhering to the regime. Also 3 patients developed coronary occlusion within the first few days or weeks after having been started on the diet and were therefore excluded. Thus, there were 34 patients with essential hypertension who co-operated and were considered satisfactory for the report.

These 34 patients had had well established known hypertension for at least three or more years. Many of them had been under personal observation during this time, others had been under the care of other physicians. Of this number 21 were

\*Presented at the annual meeting of the Massachusetts Medical Society, Boston, May 26, 1948.

women, and 13 were men. They varied in age from 35 to 69 years (Table 2)

### METHODS

Before being started on the diet, each patient had a physical examination that included an electrocardiogram, blood counts, urinalysis and determinations of twenty-four-hour urinary chloride excretion, blood cholesterol, blood urea nitrogen, total protein, albumin-globulin ratio and blood chloride. Each patient received a copy of the rice diet,\* as devised by Kempner,<sup>5</sup> which contains in 2000 calories not more than 5 gm of fat and about 20 gm of protein derived from rice and fruit and not more than 200 mg of chloride and 150 mg of sodium.

A patient takes an average of 250 to 350 gm of rice (dry weight) daily, any kind of rice may be used provided no sodium, chloride, milk, etc has been added during its processing. All fruit juices and fruits are allowed, with the exception of nuts, dates, avocados and any dried or canned fruit or fruit derivatives to which substances other than white sugar have been added. Usually no water is given and the fluid intake is limited to 700 to 1,000 cc of fruit juice per day.

Supplementary multiple vitamins were added, usually 2 unicaps per day, and iron when the patient was menstruating. Modified diets were outlined, mimeographed and ready for the patients' use as soon as their condition indicated. Directions for collecting the twenty-four-hour specimen of urine were also printed. It was believed that it was necessary to see these patients in the early part of the regime at least every two weeks to collect the twenty-four-hour specimen of urine for urinary chloride determinations as advised by Kempner,<sup>1-4</sup> secondly, merely to establish the diet in some cases and, thirdly, as in most cases, to maintain the diet and keep it varied. Patients who were perhaps too ill at the time, who for some other reason were unable to report for a regular two-week checkup or who because of psychologic reasons were having difficulty following the regime were seen by a volunteer worker (M. B. R.) at regular intervals in their homes. She answered any question about the use and preparation of the diet, collected the urine and blood specimens, recorded the blood pressure and pulse and took an electrocardiogram when it was considered necessary. One of her important duties on these visits was reassurance to the patient, making it understood that in most cases the diet was effective, that it was not necessarily a permanent one

and that although they might have periods of extreme weakness and fatigue, and even depression, they would soon feel better. This plan worked very well, and it is believed that many patients who would otherwise not have adhered to the diet followed the regime faithfully and even cheerfully.

All sedation and medication were withdrawn from these patients as soon as possible, especially from those who were taking sodium pentobarbital or phenobarbital. The patients were expected to remain rigidly on the strict rice diet for a period of three months unless a satisfactory drop in blood pressure occurred before that time. With some patients, because of their age or for psychologic reasons, it was necessary to modify the diet before the three-month period had elapsed. Patients who, during this period, had remained strictly on the diet and who also had satisfactory urinary chloride excretions but whose blood pressure did not show significant drop were considered "failures," and the diet regime was concluded.

The diet was gradually modified for patients whose blood-pressure readings dropped satisfactorily. The first modification was the addition of one egg once a week, half a cup of nonleguminous vegetables (carrots, broccoli, celery, cabbage, asparagus, beets, spinach and so forth), boiled without salt, once a day and, if desired, a cup of coffee or tea once a day, with sugar, but without milk or cream, no salt or fat was included in any of the modifications, all of which contained the amounts of rice specified above. The patient stayed on this regime for two weeks to a month. If the blood-pressure readings were satisfactory at the end of this time, 4 ounces of lean meat, fish, liver or chicken three times weekly was added to the diet, the egg being taken three times a week and the nonleguminous vegetable once a day. The meat or fish was boiled or broiled, without salt or salt-containing substances. At this time, some patients were allowed salt-free bread,<sup>†</sup> two slices daily. If progress was satisfactory after another month, the diet was again modified, to allow 4 ounces of meat and so forth as mentioned above at one meal daily, half a cup each of two nonleguminous vegetables, one egg, either boiled or poached, three times weekly, and a baked or boiled white or sweet potato twice weekly. The fourth modification of the diet<sup>‡</sup> was advised only for those patients whose blood-pressure readings had remained satisfactory after having been on the third modification for a month. This addition consisted of one egg daily if desired,

<sup>†</sup>Through the courtesy of Mr. Herbert Carlough this bread which contains only flour, yeast, sugar, vegetable shortening and water was made available by the Betty Bakerie Company.

<sup>‡</sup>This consisted of 1 egg three times a week (boiled or poached), ½ lb of lean meat, fish, chicken or liver four times a week (4 ounces with one meal), a small amount of nonleguminous vegetable seven times a week (½ cup), a small amount of white or sweet potatoes seven times a week (½ cup), boiled without salt and 1 slice of salt free bread with each meal.

No fluids except those listed with the rice diet were included. Vitamins and iron were continued.

Other alterations on discretion of physician.

\*Breakfast consisted of 2 or 3 ounces of rice (uncooked weight) with sugar or honey, two thirds of a glass of prune juice, a baked apple and a baked grapefruit. At 10 a.m. half a glass of orange juice was included with grapes and an orange. Lunch consisted of rice (as at breakfast) with sugar or honey, five eighths of a glass of orange juice, one split banana with six slices of apple, a good many raisins and a baked slice of fresh pineapple with a cherry in the center. At 3 p.m. half a glass of orange juice, apple with a cherry and an apple were taken. Supper consisted of the rice, dried soft peaches, two thirds of a glass of orange juice and a fruit plate with sugar or honey. At 9 p.m. half a glass of orange juice was taken.

meat and so forth once daily, any of the nonleguminous vegetables as desired, and a baked or boiled potato each day.

The blood-pressure readings were always taken in the same manner. Three readings were taken at intervals of five or ten minutes with the patient in the recumbent position. A mercury sphygmomanometer was always used, and the readings taken from the right arm. An average of the three readings was considered the actual reading for that visit. In the beginning of the regime, the patients were seen every two weeks for an accurate check on the blood pressure and for collection of a twenty-four-hour urine specimen. Determinations of the blood urea nitrogen, blood chloride, total protein, albumin-globulin ratio and blood cholesterol were done at monthly intervals.

### RESULTS

All the patients lost weight during the first and second months. The amount of weight loss depended upon the weight initially, but a loss of 10 to 15 pounds during this period was not unusual. The average weight of the patients was 155 pounds at the beginning, 146 pounds six weeks later and 144 pounds after three months — an average loss of 11 pounds per patient (Fig 1). Although after six months the average weight of the group was only 139 pounds, it did not mean that the patients were continuing to lose weight during the entire period, but rather that the failures had been excluded after three months. None of these patients were obese. In this series, the obese patients failed to co-operate.

The urinary chloride determinations averaged 8.6 gm before the diet was started. This dropped rapidly, going below 1 gm within the first two weeks and less than 0.5 gm within the first six-week period (Fig 1), and in some patients as low as 0.1 gm. As the diet was modified, the urinary chloride began to rise, reaching an average of 1.10 gm shortly after the three-month period, and 1.31 gm at the end of the six-month period.

The blood-pressure readings in the patients with essential hypertension averaged 210 systolic, 120 diastolic, before the regime was started, the highest being 260 systolic, 160 diastolic, and the lowest, 190 systolic, 102 diastolic. At three months, the average figure read 158 systolic, 100 diastolic. The same average figures were obtained at the end of the six-month period.

The systolic blood pressure dropped to 150 or below and the diastolic to 100 or below in 16 patients (10 women and 6 men). The blood pressure dropped 50 or more systolic and 20 or more diastolic in 8 patients (2 men and 6 women) (Table 2). Twenty-four patients, or 70 per cent, showed a definite and persistent drop in blood pressure.

The lowest readings were observed between the sixth week and the third month of the regime, while the patient was on the strict rice diet. As the diet was modified, a slight elevation of the blood pressure was observed, but in none of the successful cases did the pressure return to its original level.

The blood-pressure figures show no change from those obtained at the end of the third and sixth months, although the 10 cases of failure were excluded from the study after the three-month period (Fig 1). This is explained by the fact that the average blood-pressure readings in the successful group were lower at the three-month period while the patients were on the strict rice diet than

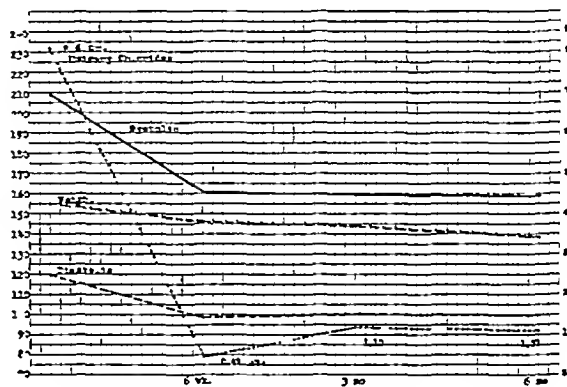

FIGURE 1 Blood-Pressure Readings in 34 Cases of Essential Hypertension (including Failures)

at the sixth-month period after the diet had been modified.

The blood chemistry was determined in each case every month for the first three months. None of the patients showed any change, with the exception of a decrease in the average cholesterol concentration in some cases. None of the patients observed developed a sodium or a chloride deficiency. During the hot summer months, these patients suffered no more from the heat than persons on normal diets. As a matter of fact, several of them maintained that they had a better summer than they had had in years.

All the patients experienced a period of weakness, which generally occurred from about the tenth to the twenty-first day and in some cases was even accompanied by a psychologic depression that required much understanding on the part of the physician and the volunteer worker. This period was only temporary, however, lasting at the most two or three weeks, and although no change was made in the diet, the patient began to feel stronger, and because of the reduction in blood pressure and absence of symptoms, all the patients felt increasingly better — far better than they had felt before the diet. It was very gratifying to find an absence

of headaches, when they had been the predominating complaint, much less tension and nervousness, these people were finally able to relax, rest and sleep well without sedation

### CASE REPORTS

**CASE 1** V L, a 49-year-old man, was first seen in 1937 for an unrelated illness. At this time, his blood-pressure reading was 130/80 (Fig 2). The patient was seen at various intervals, but it was not until some time in 1943, when his chief complaint was severe headache, that he was found to have hypertension, with a reading of 190/110. He was admitted to the hospital, where all findings were normal except for hypertension. During subsequent years, his blood pressure continued to be elevated. On April 5, 1947, when it was found to be 220/120, he was placed on the rice diet. One month later, his blood pressure was 180/120, and the headache had somewhat abated. His blood pressure continued to drop, and on June 14 it was 140/95. He was started on the second modification of the diet and was advised that he could eat one slice of salt-free bread with each meal, but through some misunderstanding ate regular bread. When he was next seen on September 20, his blood pressure had risen to 160/100. The patient, at his next visit on December 13,

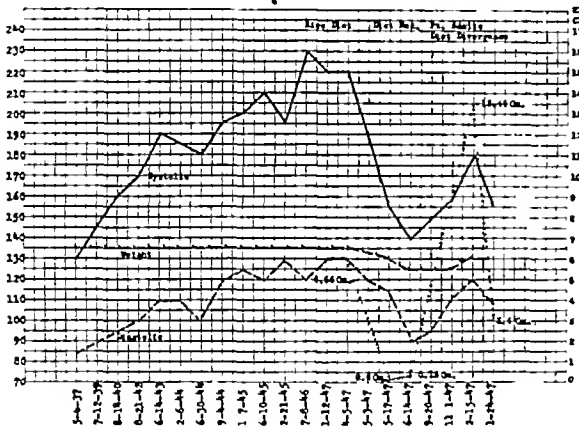

FIGURE 2 Blood Pressure and Other Data in Case 1

admitted to irregularities in his diet, which were quite obvious. His blood pressure had risen to 180/120, and the urinary chloride excretion, which had been 3 gm, was now 13.48 gm. He had also had a recurrence of severe headache. He was advised to return to his diet, which he did, and when he was last seen on January 24, 1948, his blood pressure was 155/110, and the urinary chloride excretion was 3.48 gm. His headache had again disappeared.

**CASE 2** R M, a 45-year-old woman, was first seen in 1945. She had been admitted to the Peter Bent Brigham Hospital for a surgical condition in 1943, when her blood pressure was 164/118. In the intervening years, her blood pressure varied from 180/96 to 200/115 (Fig 3). She was readmitted to the hospital for study of the hypertension in April, 1946, when her blood pressure was 180/100. All other findings were normal and she was discharged. On December 26 her blood pressure was 190/110. She was started on the rice diet on June 24, when her blood pressure was 204/110. From this date her blood pressure dropped spectacularly. On July 24, 1947, it had decreased to 150/85, and she had lost 13 pounds from her former weight of 153 pounds. Because of this favorable response, she was allowed the third modification of the diet. During a vacation, she indulged in food other than the diet, and on September 18, her blood pressure was found to be 155/92 and her urinary chloride excretion, which had been below 1 gm, had increased to 4.5 gm. She was again placed on the strict rice diet, and by January 6, 1948, her blood pres-

sure had decreased to 135/86, and the urinary chloride excretion to 0.4 gm.

**CASE 3** A P, a 65-year-old woman, was first seen in June, 1943, when her blood pressure was 210/110, with a history of known hypertension for 10 years before this visit. Her

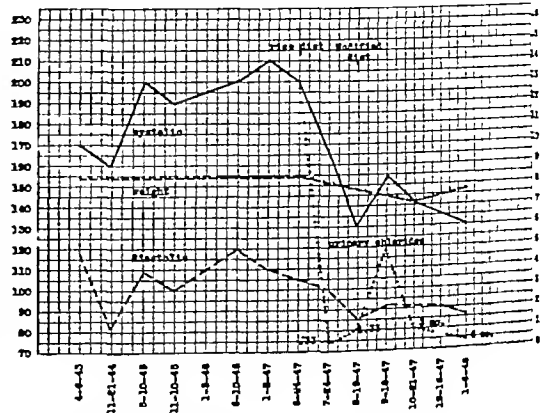

FIGURE 3 Blood Pressure and Other Data in Case 3

main complaint was a "pressure band" across the back of her head, which she stated had been present for approximately 15 years. A period of rest and small doses of phenobarbital were advised. At yearly examinations, her blood pressure readings varied between 198/118 and 230/110. In June, 1947, her blood pressure was 230/130, and she was started on the rice diet. After 2 weeks, her blood pressure was 180/110. After 6 weeks on the diet, her blood pressure had decreased to 150/90, and she felt much improved. She no longer complained of the pressure sensation in her head. Upon her next examination (August 16, 1947), her blood pressure was 130/90, and she was placed on a modified diet, which included meat, fish, vegetables and salt-free bread. The patient looked and felt markedly improved, and was capable of much more physical exertion than she had been for years. On September 16 her blood pressure was 150/100. These

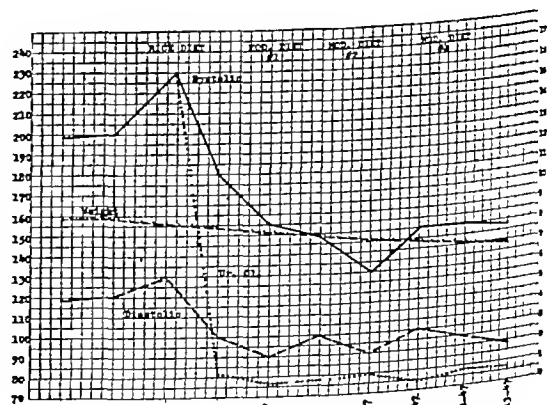

FIGURE 4 Blood Pressure and Other Data in Case 4

figures have been maintained (Fig 4), and although her diet has been modified to allow meat, vegetables and salt-free bread each day, the urinary chloride excretion has remained below 0.7 gm.

**CASE 4** T R, a 53-year-old woman with known hypertension since 1937, was first examined in 1943, 6 months after

a cerebral accident with left-sided hemiplegia. At this time, her blood pressure was 230/150. Kidney-function tests were negative, and she had no cardiac symptoms. She weighed 180 pounds and was advised to go on a diet. During the following year she lost 15 pounds, with only a slight decrease in blood pressure. She was started on the rice diet on April 20, 1947, when her blood pressure was 190/140 and the urinary chloride excretion was 118 gm. Two months later, her blood pressure had decreased to 138/102, and the urinary chloride excretion to 0.103 gm. The diet was modified at this time and despite an elevation of the urinary chloride excretion, her blood pressure has remained satisfactory (Fig 5). When she was last examined on December 13, 1947, the blood pressure was 142/105.

CASE 5 F G, a 69-year-old man, demonstrated a rapid drop in blood pressure and urinary chloride excretion with a subsequent rise in both after the diet was modified. When first seen he had a blood pressure of 220/110 and a urinary chloride excretion of 11.65 gm. During the previous 6 months, he had experienced precordial pain, suggestive of angina pectoris, and breathlessness on exertion. Kidney-function tests were negative. Although the patient was not working he was ambulatory, and no other change in his routine was prescribed with the exception of the rice diet. Ten days later, his blood pressure had decreased to 174/92, and the urinary chloride excretion to 0.79 gm. On November

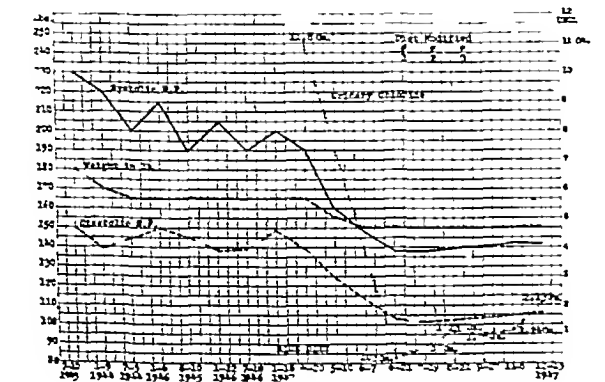

FIGURE 5 Blood Pressure and Other Data in Case 4

16 1947, his blood pressure was 128/80, the urinary chloride excretion was 0.20 gm, and the patient had lost 14 pounds. The diet was modified at this time, and on December 30, his blood pressure was 148/85, and the urinary chloride excretion was 2.08 gm. The chart on this patient ends with the December date (Fig 6). However, he has been checked twice since that time, which brings his record up to a six-month interval. On February 24, 1948, the blood pressure was 150/84, and the urinary chloride excretion was 4.77 gm. On April 7, when the patient was last seen, the blood pressure was 176/92, and the urinary chloride excretion was 4.31 gm. Although this patient admitted to some slight deviations from his diet, which might very well account for the increase in the urinary chloride excretion, it was decided to allow him to continue on the modified regime since he was feeling so much better and had returned to work.

DISCUSSION

The rice diet has been found to be a practical, inexpensive and simple method for reducing blood pressure. It requires, however, understanding and co-operation on the part of the patient to maintain it strictly, since it is a rigid departure from what is usually considered a "normal" diet. Nevertheless, of the total number of patients who have

been advised to go on the rice diet, the number of those who have refused to co-operate has been relatively small. All the patients lost weight more or less markedly during the first ten to twenty days, depending on their initial weight and the amount of edema present (Fig 1). In most cases, the loss of weight was welcomed and, at a certain place in the regime, became stabilized. Patients who were

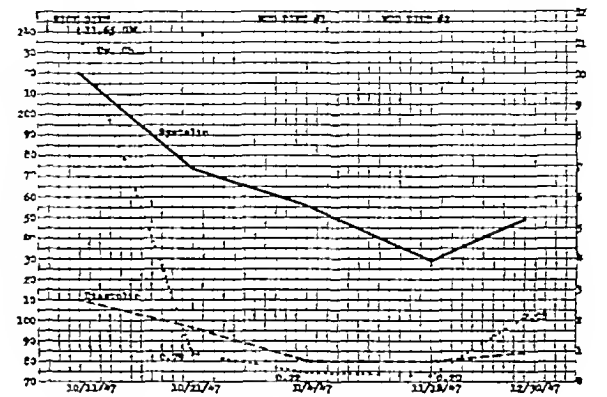

FIGURE 6 Blood Pressure and Other Data in Case 5

underweight initially lost less than those who were overweight, but this condition likewise became adjusted as the routine progressed. It is my opinion that loss of weight has little or nothing to do with a drop in blood pressure, for several of the patients who were overweight had formerly been placed on low-calorie diets, and their blood pressure had not measurably altered. On the subject of weight loss, Kempner<sup>1</sup> has the following to say:

It is not unusual for the weight to decrease more or less markedly during the first twenty days. The reason for this weight loss may be that the amount of food given does not cover the caloric requirements, in such cases, the amount of food must be increased, unless reduction of weight is indicated. Another reason may be that the patient does not eat the full amount of his diet during the first period of adjustment. The most frequent cause is the loss of visible edema, one patient with marked edema for example, lost 65 lbs. within the first sixteen days on the diet.

Urinary chloride determinations done before the patients were started on the diet averaged 8.6 gm, the lowest being 3.2 gm and the highest 13 gm. The great majority who adhered strictly to the diet had an excretion of less than 1 gm after the first two weeks. At the end of one month, the determinations were between 0.2 and 0.15 gm.

Too much emphasis cannot be placed on the necessity for obtaining the urinary chloride determinations at two-week intervals. Aside from the value to the physician, scientifically it is a valuable psychologic aid in maintaining the patient on the strict rice diet. Since it is obviously natural for patients to desire other food than that prescribed, it is carefully explained that any deviation from the

of headaches, when they had been the predominating complaint, much less tension and nervousness, these people were finally able to relax, rest and sleep well without sedation

### CASE REPORTS

**CASE 1** A L, a 49-year-old man, was first seen in 1937 for an unrelated illness. At this time, his blood-pressure reading was 130/80 (Fig 2). The patient was seen at various intervals, but it was not until some time in 1943, when his chief complaint was severe headache, that he was found to have hypertension, with a reading of 190/110. He was admitted to the hospital, where all findings were normal except for hypertension. During subsequent years, his blood pressure continued to be elevated. On April 5, 1947, when it was found to be 220/120, he was placed on the rice diet. One month later, his blood pressure was 180/120, and the headache had somewhat abated. His blood pressure continued to drop, and on June 14 it was 140/95. He was started on the second modification of the diet and was advised that he could eat one slice of salt-free bread with each meal, but through some misunderstanding ate regular bread. When he was next seen on September 20, his blood pressure had risen to 160/100. The patient, at his next visit on December 13,

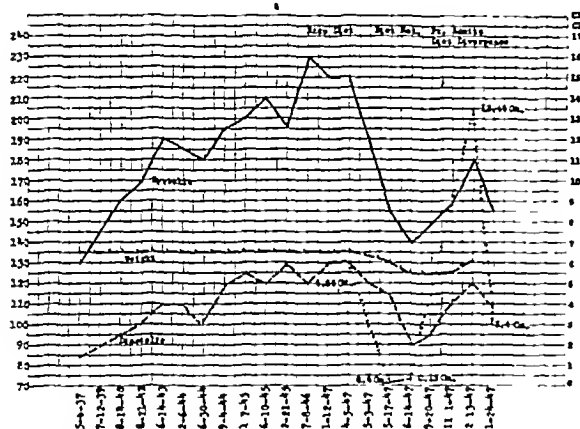

FIGURE 2 Blood Pressure and Other Data in Case 1

admitted to irregularities in his diet, which were quite obvious. His blood pressure had risen to 180/120, and the urinary chloride excretion, which had been 5 gm, was now 13.48 gm. He had also had a recurrence of severe headache. He was advised to return to his diet, which he did, and when he was last seen on January 24, 1948, his blood pressure was 155/110, and the urinary chloride excretion was 3.48 gm. His headache had again disappeared.

**CASE 2** R M, a 45-year-old woman, was first seen in 1945. She had been admitted to the Peter Bent Brigham Hospital for a surgical condition in 1943 when her blood pressure was 164/118. In the intervening years, her blood pressure varied from 180/96 to 200/115 (Fig 3). She was readmitted to the hospital for study of the hypertension in April, 1946, when her blood pressure was 180/100. All other findings were normal and she was discharged. On December 26 her blood pressure was 190/110. She was started on the rice diet on June 24 when her blood pressure was 204/110. From this date her blood pressure dropped spectacularly. On July 24, 1947, it had decreased to 150/85, and she had lost 15 pounds from her former weight of 155 pounds. Because of this favorable response, she was allowed the third modification of the diet. During a vacation, she indulged in food other than the diet, and on September 18, her blood pressure was found to be 155/92 and her urinary chloride excretion, which had been below 1 gm, had increased to 4.5 gm. She was again placed on the strict rice diet, and by January 6, 1948 her blood pres-

sure had decreased to 135/86, and the urinary chloride excretion to 0.4 gm.

**CASE 3** A P, a 65-year-old woman, was first seen in June 1943, when her blood pressure was 210/110, with a history of known hypertension for 10 years before this visit. Her

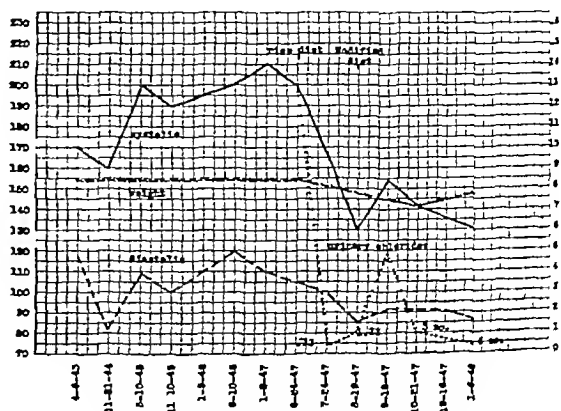

FIGURE 3 Blood Pressure and Other Data in Case 2

main complaint was a "pressure band" across the back of her head, which she stated had been present for approximately 15 years. A period of rest and small doses of phenobarbital were advised. At yearly examinations, her blood pressure readings varied between 198/118 and 230/130. In June, 1947, her blood pressure was 230/130, and she was started on the rice diet. After 2 weeks, her blood pressure was 180/110. After 6 weeks on the diet, her blood pressure had decreased to 150/90, and she felt much improved. She no longer complained of the pressure sensation in her head. Upon her next examination (August 16, 1947), her blood pressure was 130/90, and she was placed on a modified diet, which included meat, fish, vegetables and salt-free bread. The patient looked and felt markedly improved, and was capable of much more physical exertion than she had been for years. On September 16 her blood pressure was 150/100. These

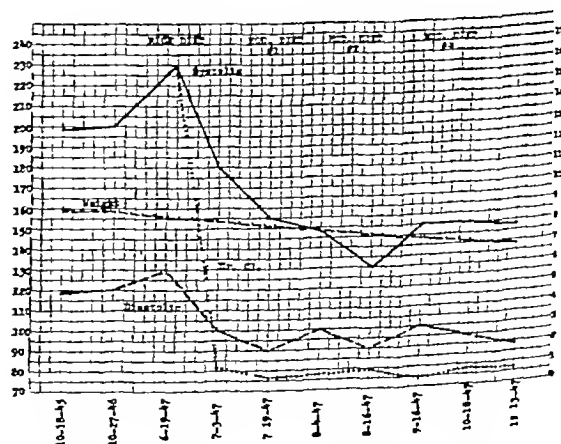

FIGURE 4 Blood Pressure and Other Data in Case 3

figures have been maintained (Fig 4), and although her diet has been modified to allow meat, vegetables and salt-free bread each day, the urinary chloride excretion has remained below 0.7 gm.

**CASE 4** T R, a 53-year-old woman with known hypertension since 1937, was first examined in 1945, 6 months after

a cerebral accident with left-sided hemiplegia. At this time, her blood pressure was 230/150. Kidney-function tests were negative, and she had no cardiac symptoms. She weighed 180 pounds and was advised to go on a diet. During the following year she lost 15 pounds, with only a slight decrease in blood pressure. She was started on the rice diet on April 20, 1947, when her blood pressure was 190/140 and the urinary chloride excretion was 118 gm. Two months later, her blood pressure had decreased to 138/102, and the urinary chloride excretion to 0.103 gm. The diet was modified at this time, and despite an elevation of the urinary chloride excretion, her blood pressure has remained satisfactory (Fig 5). When she was last examined on December 13, 1947, the blood pressure was 142/105.

CASE 5 F G, a 69-year-old man, demonstrated a rapid drop in blood pressure and urinary chloride excretion with a subsequent rise in both after the diet was modified. When first seen he had a blood pressure of 220/110 and a urinary chloride excretion of 11.65 gm. During the previous 6 months, he had experienced precordial pain, suggestive of angina pectoris, and breathlessness on exertion. Kidney-function tests were negative. Although the patient was not working he was ambulatory, and no other change in his routine was prescribed with the exception of the rice diet. Ten days later, his blood pressure had decreased to 174/92, and the urinary chloride excretion to 0.79 gm. On November

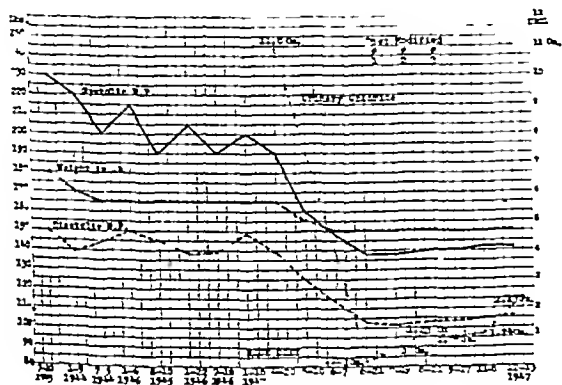

FIGURE 5 Blood Pressure and Other Data in Case 4

18, 1947, his blood pressure was 128/80, the urinary chloride excretion was 0.20 gm, and the patient had lost 14 pounds. The diet was modified at this time, and on December 30, his blood pressure was 148/85, and the urinary chloride excretion was 2.08 gm. The chart on this patient ends with the December date (Fig 6). However, he has been checked twice since that time, which brings his record up to a six-month interval. On February 24, 1948, the blood pressure was 150/84, and the urinary chloride excretion was 4.77 gm. On April 7, when the patient was last seen, the blood pressure was 176/92, and the urinary chloride excretion was 4.51 gm. Although this patient admitted to some slight deviations from his diet, which might very well account for the increase in the urinary chloride excretion, it was decided to allow him to continue on the modified regime since he was feeling so much better and had returned to work.

### DISCUSSION

The rice diet has been found to be a practical, inexpensive and simple method for reducing blood pressure. It requires, however, understanding and co-operation on the part of the patient to maintain it strictly, since it is a rigid departure from what is usually considered a "normal" diet. Nevertheless, of the total number of patients who have

been advised to go on the rice diet, the number of those who have refused to co-operate has been relatively small.

All the patients lost weight more or less markedly during the first ten to twenty days, depending on their initial weight and the amount of edema present (Fig 1). In most cases, the loss of weight was welcomed and, at a certain place in the regime, became stabilized. Patients who were

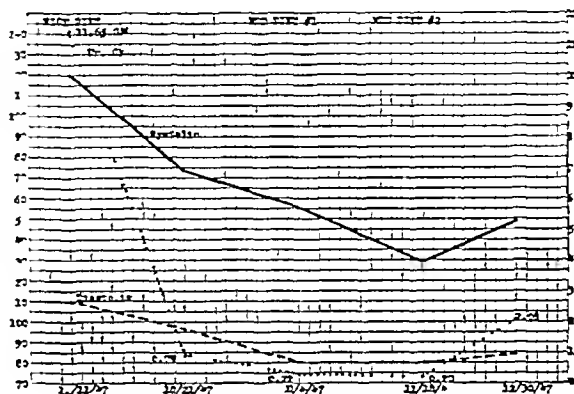

FIGURE 6 Blood Pressure and Other Data in Case 5

underweight initially lost less than those who were overweight, but this condition likewise became adjusted as the routine progressed. It is my opinion that loss of weight has little or nothing to do with a drop in blood pressure for several of the patients who were overweight had formerly been placed on low-calorie diets, and their blood pressure had not measurably altered. On the subject of weight loss, Kempner<sup>1</sup> has the following to say:

It is not unusual for the weight to decrease more or less markedly during the first twenty days. The reason for this weight loss may be that the amount of food given does not cover the caloric requirements, in such cases, the amount of food must be increased, unless reduction of weight is indicated. Another reason may be that the patient does not eat the full amount of his diet during the first period of adjustment. The most frequent cause is the loss of visible edema: one patient with marked edema for example, lost 65 lbs within the first sixteen days on the diet.

Urinary chloride determinations done before the patients were started on the diet averaged 8.6 gm, the lowest being 3.2 gm and the highest 13 gm. The great majority who adhered strictly to the diet had an excretion of less than 1 gm after the first two weeks. At the end of one month, the determinations were between 0.2 and 0.15 gm.

Too much emphasis cannot be placed on the necessity for obtaining the urinary chloride determinations at two-week intervals. Aside from the value to the physician, scientifically, it is a valuable psychologic aid in maintaining the patient on the strict rice diet. Since it is obviously natural for patients to desire other food than that prescribed it is carefully explained that any deviation from the

strict diet will be easily observed in these tests. This advice, in my experience, has proved an inhibitory factor in some patients whose need and desire for a varied menu was greater than that in others.

I have learned many things from my experience with a rather large number of patients on this diet. One of the most conspicuous problems is that it is difficult if not impossible to have a patient revert to the strict rice diet if the results on the modified diet have proved unsatisfactory. In the future, it will be necessary to maintain certain patients for a longer period on the strict rice diet. Also, the modified diets have been considerably altered to eliminate eggs, liver and certain nonleguminous vegetables high in sodium content—notably, spinach, beets and kale. The new modified diets add considerably less in quantity at each modification, and there are six diets instead of four. The results of these changes will be discussed in a subsequent publication.

Although these observations cover a limited period, it is my belief that the rice diet for hyper-

tension offers the greatest hope so far for the medical treatment of a disease in which, to date, the therapeutic results have been notoriously poor.

The mechanism through which the reduction of blood pressure is achieved is not known, but it is difficult to escape the notion that the sodium ion<sup>6-8</sup> plays a role in a manner not yet clear.

## THYROID THERAPY IN GYNECOLOGIC ABNORMALITIES\*

C L BUXTON, M D,† AND F H VANN, M D‡

NEW YORK CITY

FOR a number of years it has been the impression of obstetricians and gynecologists that lack of thyroid activity has a definite influence on the production of menstrual and obstetric abnormalities.

It has been said that "the relation of the thyroid gland to the sex organs is the most ancient and classical interrelation of the functions of the glands of internal secretion. Known to the ancients and a subject of daily gossip, it has passed down through the ages."<sup>1</sup>

In 1926 Litzenberg<sup>2</sup> noted the frequency of low basal metabolic rates in patients complaining of sterility and menstrual abnormalities, and in 1929 Litzenberg and Carey<sup>3</sup> reported 91 cases of sterility with low basal metabolic rates in 52. Of these, 36 per cent had abnormal menstruation, and 30 per cent conceived after thyroid medication. There were 2 abortions. Somewhat similar results were published by Haines and Mussey<sup>4</sup> in 1935 on 74 cases, some of which had been reported before, with menstrual abnormalities and low basal metabolic rates but no evidence of myxedema. This type of

case has come to be known, correctly or not, by the name of "subclinical hypothyroidism."

Of their 74 patients, 59 complained of amenorrhea or oligomenorrhea, and 15 of menorrhagia. The basal metabolic rates varied in these patients, but none were less than -30 per cent and no patient had symptoms of myxedema. The resumption of normal menstruation following thyroid therapy occurred in about 60 per cent of patients with hypomenorrhea and in 53 per cent of those with menorrhagia.

It will be noted that 80 per cent of the menstrual abnormalities in these patients consisted of a decrease in menstrual activity as measured by amount, duration and frequency of menstrual flow.

On the other hand, Mason<sup>5</sup> found, in patients with so-called "subclinical hypothyroidism," frequent abnormal menstruation rather than actual amenorrhea, and Hamblen and his co-workers,<sup>6</sup> although finding no significant change in the actual bleeding from secretory endometrium in hypothyroidism, noticed a greater infrequency of menstrual periods. In discussing the apparent increased incidence of abortion in hypothyroid patients, the authors speak of the possible gametopathic effect of lowered oxygen metabolism due to lack of thyroid activity.

In discussions of papers in the gynecologic-endocrine literature it has become almost a common-

place to state that thyroid medication is still the only trustworthy and efficacious hormonal preparation available for the treatment of menstrual disturbances. Furthermore, it is the general opinion of many gynecologists that the menstrual disturbances of hypothyroidism are those of hypomenorrhea — that is, absent or decreased menstruation — rather than profuse menstrual flow. On the other hand, the impression that decreased thyroid activity results in menorrhagia is a common one among internists, and Means<sup>7</sup> states this to be so in discussing menstrual abnormalities and diseases of the thyroid gland. In the same textbook, however, he quotes the observation of Haines and Mussey that hypomenorrhea is four times more frequent than hypermenorrhea in "subclinical hypothyroidism."

In an effort to determine experimentally the effect of hypothyroidism on menstruation, Engle<sup>8</sup> carried out thyroidectomies on 3 monkeys that had previously had normal menstrual cycles. Amenorrhea occurred in hypothyroid monkeys with intact

it more closely and to evaluate the result of thyroid therapy.

A review and analysis were therefore made of 550 consecutive patients seen in the sterility and

ovaries, normal cyclic menstruation being re-established by thyroid administration.

Since there is some question regarding not only the actual clinical entity of this group of patients who have slightly low basal metabolic rates and menstrual abnormalities but also just what their menstrual abnormalities are, it was decided to review a number of cases from the Sloane Hospital sterility and endocrine clinic in an attempt actually to identify this type of clinical picture, to define

who received thyroid medication were considered in this review. One hundred and fourteen patients, or 20.7 per cent, had received medication in addition to thyroid, so that they could not be considered in the results. Fifty-three of these cases were not followed. Sixty-one patients, or 11 per cent of the original 550, had received thyroid medication exclusively and their progress had been sufficiently observed to warrant accurate conclusions about results. Their classification accord-

ing to diagnoses and basal metabolic rates is presented in Table 1. Serum cholesterol studies were made in 35 of these patients. Of these, only 6 were above 225 mg per 100 cc.

It must be stressed that these patients were actually a selected group in that they were given thyroid medication during their course of investigation and treatment in the clinic. It is therefore assumed that the clinician who saw them believed that thyroid medication was indicated. The great majority of the 550 cases reviewed did not receive thyroid therapy. This is especially significant in the small groups in this series, such as the cases of dys-

menstrual disturbances, that there is a fairly common condition of mild thyroid deficiency, usually known as "subclinical hypothyroidism," that is amenable to thyroid therapy. This condition, which is sort of "twilight zone" between the normal gland and a state of myxedema, is characterized by symptoms suggestive of decreased metabolic activity such as weight gain, lassitude, dry skin, brittle fingernails, coarse hair and, what is most important to gynecologists, menstrual abnormality—decreased menstrual activity in the great majority of cases. Furthermore the basal metabolic

menorrhea and habitual abortion. Most patients with similar complaints were treated by other techniques so that the few who fell into the category of thyroid-treated cases are thought to have more significance than their numerical paucity admits.

The results of thyroid therapy are shown in Table 2. It would be incorrect to ascribe all pregnancies and all cures in these different groups to thyroid therapy alone. Certainly, in the cases of sterility there must be a certain percentage of patients who would have become pregnant during the course of investigation without any therapy whatever (3 out of 13 in a recent series of 52 cases of sterility). However, the patients placed on thyroid therapy had all finished their investigation, and the sterility had lasted from fourteen months to ten years.

Of the menstrual abnormalities it is certainly true that spontaneous remissions—or resumption of menstruation in cases of amenorrhea—occur, and undoubtedly a certain percentage of these patients would have spontaneously resumed normal menstruation. Most of them, however, had received therapy of various sorts elsewhere or in our clinic without success before receiving thyroid.

Table 3 compares our results with those reported elsewhere. It will be seen that for the most part the figures are fairly comparable.

### DISCUSSION

The cases presented add corroborative evidence to the impression long held by physicians treating

rates and blood cholesterol determinations are, for the most part, not significantly abnormal.

Not the least of the significant relations between possible thyroid deficiency and this type of case is the appreciable number of patients improved by thyroid therapy. Not only in this series but also in others previously reported, there has been a fair percentage of cures in patients who received thyroid therapy only. This is especially true in the series of cases of sterility.

It seems legitimate to conclude, therefore, that thyroid therapy is advantageous in many cases of abnormal menstruation and sterility even in the presence of fairly normal basal metabolic rates. These patients do not have signs of myxedema and tolerate fairly large dosages of thyroid.

## TRAUMATIC PARTIAL LOBECTOMY FROM GUNSHOT WOUND\*

## Report of a Case with Recovery and Personality Change

EDGAR M. HOLMES, M.D.†

BOSTON

IN THE following case the patient received a head injury similar to that in the famous crowbar-skull case, which has been written up in the past and the skull of which is on exhibition at the Harvard Medical School Museum. In that case, a miner while tamping a hole in the ground filled with blasting powder accidentally ignited the blast, which created a projectile of the tamping crowbar. The projectile entered the head just lateral to the angle of the left ramus of the mandible, traveling

consisting of increased profanity, obstinacy and狠fulness. In the last year of his life, the patient developed convulsions followed by others and death at thirty-eight years of age.

## CASE REPORT

A 45-year-old woman had a pyramiding depression, which terminated in a suicidal attempt. To execute this, she held a 12-gauge shotgun under her chin and pulled the trigger. She was found in an unconscious state with a hole of entry in the midline of her chin about 1.5 cm. behind the symphysis

FIGURE 1 Appearance of the Patient on Admission

A shows an area in the forehead covered by irregular epithelium beneath which there is scar tissue without dura, the brain being directly beneath. There is moderate loss of forehead skin associated with retraction of the remaining tissue. (Note the displacement of the left ascending process of the superior maxilla and the lacrimal bone with a slightly visible divergence of the pupils.) The nasal bones are absent. There is a hole in the nose. B demonstrates a point of entry in the soft tissues of the chin that has closed itself. In the palate is visible the hole that was shot out. On the forehead, the depression can be seen.

medially and superiorly to find its exit near the midline, where the parietal and frontal bones meet. This man, after a stormy convalescence lived for thirteen years and was able to go about the country as a living exhibit of this most unusual accident and injury. The only residual lesion that was noticeable to others was a changed personality.

\*From the Department of Plastic Surgery, Massachusetts Eye and Ear Infirmary.

†Assistant professor of otolaryngology, Boston University School of Medicine; instructor in otology, Harvard Medical School; associate surgeon for plastic operations, Massachusetts Eye and Ear Infirmary; chief of otolaryngology, Newton Hospital.

The hole carried up through the tongue, causing torn lacerations together with areas of complete loss of substance of that organ. It continued through the hard palate, the perpendicular plate of the ethmoid, both nasal bones, the frontal sinuses and part of the frontal bone as far as the hairline (Fig. 1). Some of the forehead scalp was lost. After débridement and the use of penicillin, the patient gradually recovered.

On admission to the Massachusetts Eye and Ear Infirmary, examination revealed that the frontal defect had granulated and epithelized over and was pulsating from the underlying brain. The forehead flaps had retracted laterally. A scar left in the soft tissue of the chin had closed over the floor of the mouth. The tongue had three points, and as a result of the laceration and scarring, it was bound down and immo-

bile. It was with much difficulty that the patient could talk or eat, since her tongue could not be pulled up to the roof of her mouth. The hole in the palate remained patent and

A psychiatrist believed that the patient was perfectly oriented, without a psychosis, and that she had probably performed a partial anterior lobectomy, which had cured her pyramiding depression. Her vision was within normal limits; there had been no change after the accident other than a small tear in the right choroid.

X-ray study revealed the losses mentioned above. In addition, there were some pellets that had sprayed into the brain, one going back near the occiput (Fig. 2).

The corrective problems in this case were sevenfold: the brain needed protection, the hole into the nose should be closed, the hole in the palate should be closed, the function of her tongue would improve if the fragments were joined into one and the tongue freed so that the patient could talk

FIGURE 2. Anteroposterior View of the Skull, Showing the Loss of the Frontal Sinus and Part of the Frontal Bone. Note the dispersed, small, lead shot.

round but was closed by an upper plate. The membrane had healed over the anterior and posterior remaining parts of the septum, but there was a hole where the nasal bones should

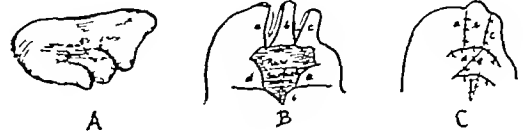

FIGURE 4. Correction of the Lacerated, Bound-Down Tongue. A represents an anterior top view of the tongue (Note the central scarred, bound down and immobile tongue with the three prongs of tissue — much of the tongue was shot away). B is a diagram of the under surface of the tongue, revealing the incisions and the raw area just after removal of much of the scar tissue and freeing of the tongue. C shows the method of closure of the under surface.

and eat with greater ease, the displaced ascending process of the left superior maxilla, the lacrimal bone and the ethmoid should be brought back in the midline in an attempt to enlarge the orbit and thus permit the eye to have a normal range of excursion and probably lessen some of the diplopia. The contour of the nose and forehead would be improved if brought out to their original level, and the left lacrimal sac must be opened and drained into the nose to correct tearing.

All operative procedures were conducted under local anesthesia except the one in which bone grafting was done, and this was performed with a general anesthetic (nitrous oxide, oxygen and ether).

The first stage consisted of exposure of the displaced left superior maxilla and ethmoid bones, which were then freed and placed back into normal position. At the same time,

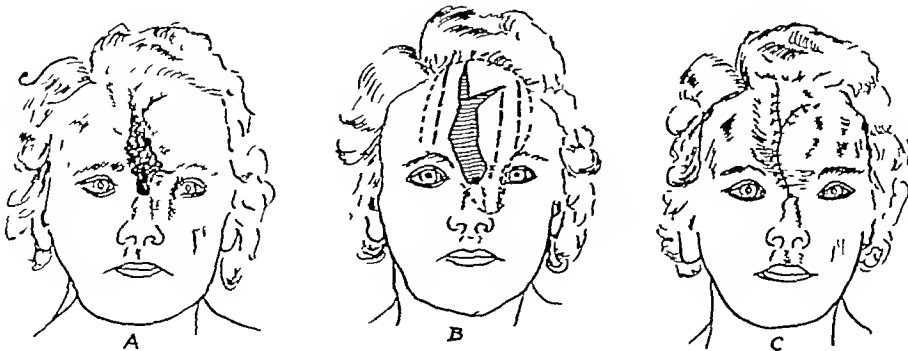

FIGURE 3. Steps in the First Operation. A shows the deformity. B demonstrates the incision (solid line), the extent of undermining (short dotted line), and the incision through the aponeurosis (long dotted line). C shows the method of closure.

have been, with a depression to the level of the inner canthus. The left ascending process, lacrimal and ethmoid bones were pushed laterally, causing a marked diplopia (Fig. 1a).

The forehead wound was closed, the epidermis that had grown over the brain being removed and the brain being covered with forehead flaps, which were freed so that they could

approximate. The opening in the nose was partially closed by direct approximation of the skin edges (Fig. 3). A few days later, the scarred and bound-down tongue was mobilized and the three points of the lacerated tongue were brought together. The scar on the undersurface was freed.

The diplopia improved objectively, but the patient still has double vision though it is less pronounced. She also continued after a couple of months, to have tearing and some infection in her left tear sac, so that a tear-sac operation was performed. As expected, there were no landmarks present,

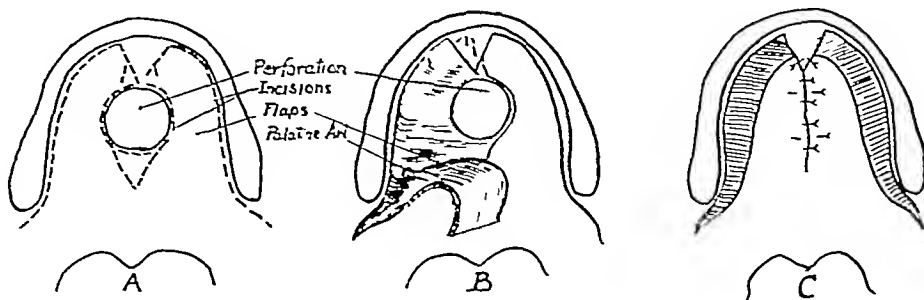

FIGURE 5 Closure of the Palatal Defect

A shows the lines of the incision (heavy dotted line). In B one palatal flap has been raised, and the palatine artery exposed and stretched from its caral. C demonstrates the method of closure.

and corrected by a "Z" plastic. This enabled the patient to talk and eat much more easily (Fig. 4). At a later stage, the hole in the palate was closed, two flaps being utilized, as in a case of cleft palate (Fig. 5). This further improved speech and facility in eating because the mouth was separated from the nose. The patient still had the hole through the dorsum

since the area of the lacrimal bone and sac were comminuted and filled with fragments of bone, callus and scarred tissue. What was left of the tear sac was freed, and this was opened and drained into the nose. Her tearing is less and the infection has gone.

FIGURE 6 The Postoperative Result

The forehead has been brought out to a normal contour. There is still some irregularity of the skin. The ascending processes and lacrimal bone and ethmoid are in place, and the nose is elevated. (Note the restoration of the nasal bone.)

of her nose and the depression caused by the loss of frontal and nasal bones. This condition was corrected by a bone graft taken from the ilium. It was unnecessary to employ skin grafting to obtain skin for the region of the glabella and the nasal dorsum (Fig. 6).

The patient is most appreciative of all that has been done for her and has resumed her place as an active member in her community.

## INFECTIOUS MONONUCLEOSIS WITH PSYCHOSIS\*

## Report of a Case

R W RAYMOND, MD,† AND R L WILLIAMS, MD‡

ALBANY, NEW YORK

**I**NVOLVEMENT of the central nervous system in infectious mononucleosis has been reported by a number of authors since the patients with meningitis described in 1931 by Johansen<sup>1</sup> and by Epstein and Dameshek.<sup>2</sup> However, cases of infectious mononucleosis associated with psychosis have not appeared up to the present time in the literature to our knowledge. Many cases of meningitis and peripheral-nerve palsies, occurring separately or together, have been reported.<sup>3-12</sup> Bernstein's<sup>13</sup> monograph summarized most of these early reports up to 1940. In 1941, while publishing the details of a case of meningeal involvement, together with ataxia, catatonia and slurred speech, Landes, Reich and Perlow<sup>14</sup> reviewed the literature with particular regard to central-nervous-system manifestations. Since that time cases of a similar nature have been added to the literature.<sup>15-25</sup> All these patients had serous meningeal findings or some other neurologic manifestation such as paralyses, convulsions or reflex changes. At times the picture simulated a Guillain-Barré syndrome.

Because the condition is rarely fatal, only a few cases of infectious mononucleosis have come to autopsy. Particular examples are those reported by Ziegler,<sup>26</sup> Allen and Kellner<sup>27</sup> and Peters et al.<sup>28</sup> All pointed out a nonspecific but definite involvement of the central nervous system with increased vascular reaction of the pia arachnoid, petechial hemorrhages in the brain and degenerative changes of the Purkinje cells. The literature since Bernstein's article has been summarized twice by Bethell et al.<sup>29, 30</sup> In reporting 2 additional cases Slade<sup>31</sup> completed a review of the literature up to 1946, which dealt with central-nervous-system involvement in infectious mononucleosis. In none of these reports can one find a case of psychosis associated with acute infectious mononucleosis.

The following case report is that of a psychotic episode resembling schizophrenia that occurred during the course of typical acute infectious mononucleosis and subsided during the regression of the disease.

## CASE REPORT

E T, a 25-year-old married college student was admitted to the Albany Hospital on December 11, 1947. He was placed on the psychiatric ward because he had become unmanageable in a neighboring hospital. The history obtained from his family revealed that he had developed general malaise,

anorexia, fatigue, headache, a temperature of 102°F and sweating, but no chills, about 16 days prior to admission. Entering the referring hospital on December 1, he had complained that his symptoms had grown progressively worse and that he had developed painful lymph nodes in his neck with some abdominal discomfort. At that time, physical examination revealed a well developed and well nourished man who was alert and co-operative with a blood pressure of 120/70, a temperature of 98.6°F and respirations of 20. Positive physical findings included injected scleras, a coated tongue, bilateral cervical lymphadenopathy in the posterior chain and several small inguinal lymph nodes. The rest of the physical examination was negative. Examination of the blood on December 1 showed a red-cell count of 4,800,000 with a hemoglobin of 90 per cent (Sahli), and a white-cell count of 4500, with 1 per cent basophils, 3 per cent eosinophils, 15 per cent stab forms, 20 per cent segmented neutrophils, 51 per cent lymphocytes and 4 per cent monocytes. Fifty per cent of the lymphocytes appeared large and abnormal. The urine was normal. On the 2nd day, heterophil-antibody agglutination was reported positive in a dilution of 1:40. Also a Widal test was reported positive in a dilution of 1:100 (the patient was a World War II veteran). No brucella agglutination was obtained.

On the fourth hospital day, repeated examination of the blood disclosed a red-cell count of 5,200,000, with a hemoglobin of 108 per cent (Sahli), and a white-cell count of 5900 with 2 per cent basophils, 1 per cent eosinophils, 10 per cent stab forms, 19 per cent segmented neutrophils, 61 per cent lymphocytes and 4 per cent monocytes. There were 2 young lymphocytes, and on this day heterophil-antibody agglutination was reported positive in a dilution of 1:60. On the 5th day the agglutination was positive in a dilution of 1:320. Examination of the spinal fluid showed a total protein of 15 mg per 100 cc. An x-ray film of the chest on admission revealed an area of increased density in the region of the hilus that was consistent with peribronchial infiltration, but not suggestive of pneumonia or tuberculosis. The course of the disease from time of entry on December 1 until transfer to the Albany Hospital was reported as most disturbing mentally. Review of the record showed that the patient was confused much of the time from the day of admission. The nurses reported that he became more irritable, often was overtalkative and showed "flight of ideas" in speech. He was demanding at times and on one occasion attempted to walk out of the hospital. He became belligerent, impulsive and unpredictable in his behavior, and once he threw a glass of water in the nurse's face. He received penicillin and sedatives during his stay, but as time passed, he became delusional, his speech was rambling, and he talked of his sex life much of the time. Because of his behavior, he was transferred to the Albany Hospital.

Physical examination was only slightly different from that previously reported. There was a papuloerythematous rash on the back. The pharynx was injected and there were dry patchy areas of denuded epithelium with a white exudate visible. The cervical lymph nodes were still enlarged but not tender. The remainder of the physical and neurologic examinations were completely within normal limits. The patient's mental status was definitely abnormal. He was overactive and overtalkative, impulsive and unpredictable. His thinking was rambling and irrelevant. He seemed preoccupied with thoughts of his family, childhood and health. No definite delusions or hallucinations were noted at this time, but his mood was often labile, and his affect seemed inappropriate. He was well oriented in time, place and person, but his insight and judgment were lacking.

The temperature was 101°F.

Urinalysis demonstrated a reaction of pH 6.5, a specific gravity of 1.020 and a trace of albumin. There was no sugar.

\*From the Department of Medicine and the Department of Neurology and Psychiatry, Albany Hospital.

‡Assistant resident in neurology and psychiatry, Albany Hospital.

acetone or urobilinogen, and microscopical examination was negative. Examination of the blood showed a red-cell count of 4,320,000, with a hemoglobin of 108 per cent (Sahli), and a white-cell count of 16,050, with 1 per cent stab forms, 24 per cent segmented neutrophils and 75 per cent lymphocytes. Many of the lymphocytes showed large amounts of pale-blue cytoplasm, with large oval nucleoli. The blood sugar was 91 mg, and the blood nonprotein nitrogen 35 mg per 100 cc. The blood Wassermann test was negative. A heterophil-antibody agglutination was positive in a dilution of 1:1792. The spinal fluid was clear and showed no cells, the total protein was 42 mg, the chloride 760 mg, and the

DISCUSSION

There was considerable controversy regarding whether this was a case of toxic psychosis associated with infectious mononucleosis, or whether there was an actual schizophrenia precipitated by the febrile illness. The diagnosis of infectious mononucleosis was certain in view of the fever, enlarged lymph nodes, abnormal lymphocytes in increased

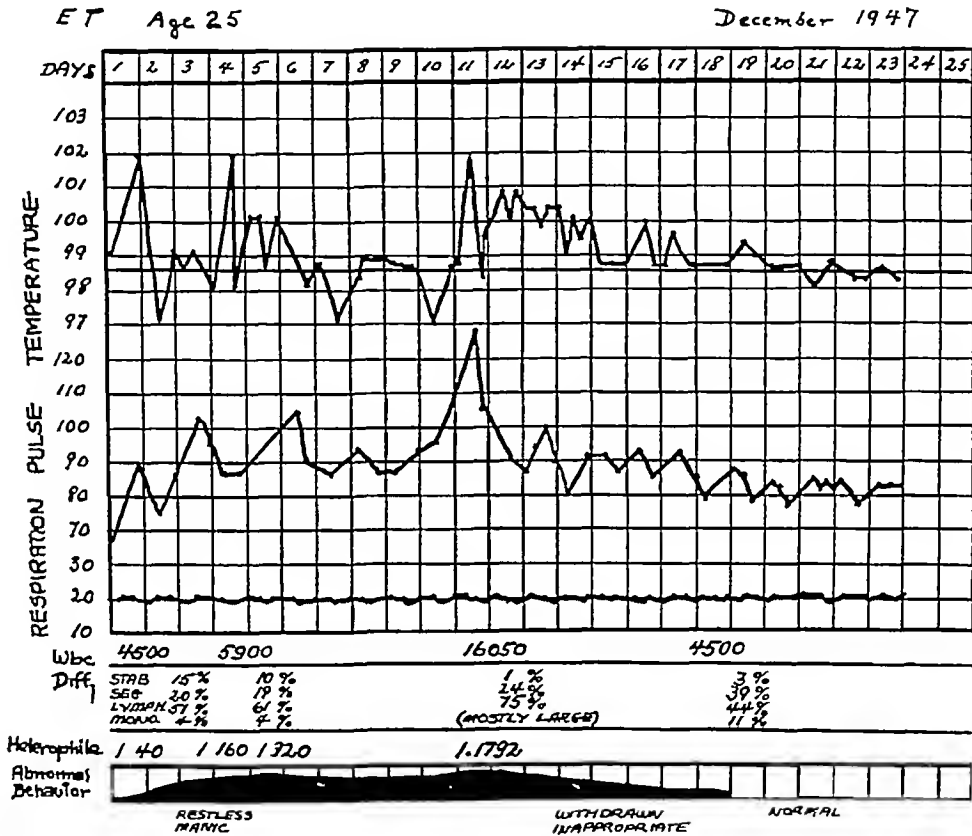

FIGURE 1 Clinical Course

sugar 66 mg per 100 cc. The spinal-fluid Wassermann test was negative, as was the colloidal-gold test.

The patient was treated symptomatically with adequate diet, fluids and sedatives. On several occasions he showed definite evidence of auditory and visual hallucinations and delusions. His behavior alternated from overactivity and excitement to withdrawal and loss of contact with his environment. The picture resembled an acute schizophrenic episode. On December 19 there was a dramatic change in his mental status. He became alert and co-operative. There was none of the overactivity or overtalkativeness. The delusions and hallucinations had completely disappeared. The temperature fell to normal on December 20 and 3 days later he was well enough to be discharged. The lymph nodes were still moderately enlarged, and the spleen was palpable three fingerbreadths below the costal margin. He was seen later for a follow-up examination, and no abnormality was found psychiatrically. The symptoms of infectious mononucleosis had subsided except for some fatigue. He went back to his college career and is doing very well leading an active social as well as scholastic life, according to a report 3 months later. The clinical course is demonstrated in Figure 1.

number and the rising titer of the heterophil-antibody agglutination. The absence of any neurologic manifestations, the failure to demonstrate pathologic changes in the cerebrospinal fluid and the dramatic resolution of the marked psychotic episode suggested that a toxic psychosis was the best explanation of the syndrome.

SUMMARY

The literature relating to central-nervous-system involvement in infectious mononucleosis is briefly reviewed and a case of this disease with a toxic psychosis resembling schizophrenia presented.

We are indebted to Dr. S. Eugene Barrera, neurologist and psychiatrist-in-chief, and to Dr. L. Whittington Gorham, physician-in-chief, Albany Hospital, for permission to report this case.

## MEDICAL PROGRESS

## BLOOD AND ITS DERIVATIVES\*

SAM T. GIBSON, M.D.†

BOSTON

SINCE prehistoric man first noticed the red fluid that issued from his wounds, much thought and energy have been expended toward the conservation, investigation and utilization of this life-symbolizing liquid—blood. The past decade has witnessed great advances along these lines impelled by the demands of the recent war. To summarize all aspects of this important subject, however, would involve a treatise on the major branches of medicine. This review is restricted to the following topics: whole blood—preservation, use, reactions, salvage of erythrocyte residues, physiology and procurement, plasma—homologous serum hepatitis and clinical use, plasma fractionation—methods, use of fractions and mechanism of action, blood substitutes, protein therapy—metabolism, administration and reactions, and laboratory methods—amino acids, total protein and protein fractions. One major subject—the Rh factor—is reserved for a separate review.<sup>1</sup>

It is intended that this will supplement previous reviews on blood and plasma proteins appearing

in the *Journal* since 1941.<sup>2-5</sup> These form a helpful background for the following general discussion. More detailed information can be obtained from many excellent reviews now available.<sup>6-18</sup>

## BLOOD

## Preservation

World War I initiated the use of blood transfusions on a large scale. Until World War II, however, technics changed little, and blood was given directly through a variety of devices or indirectly, sodium citrate being used as an anticoagulant.<sup>19</sup> The storage period of five to seven days permitted by this system was satisfactory for most hospitals, very few of which had banks, but it was totally inadequate for military use. Worldwide problems of logistics demanded a longer dating period and more stability. This difficulty was resolved early in the war by the development and use of dried plasma, dried serum and concentrated human serum albumin. Although these agents were extremely useful, increasing medical experience showed that no substitute approached the efficacy of blood in the severely wounded.<sup>6</sup> Accordingly, in 1944

\*From the Medical Clinic, Peter Bent Brigham Hospital and the Department of Medicine, Harvard Medical School.

†Milton Research Fellow in Medicine, Harvard Medical School, assistant in medicine, Peter Bent Brigham Hospital.

the Committee on Medical Research of the Office of Scientific Research and Development and the Army and Navy medical departments took up again the problem of preserving and shipping whole blood. The findings of the six major groups of investigators recently appeared simultaneously.<sup>20-31</sup>

Studying the effects of variations in reaction, temperature, buffers, concentration of glucose and volume of diluent, it was generally agreed that maximal preservation followed the use of a slightly acid citrate-dextrose solution,\* which was cooled to 4 to 10°C before the blood was collected and maintained there continuously thereafter. A formula utilizing these principles had already been proposed by Loutit and Mollison.<sup>22</sup> Using erythrocytes tagged with radioactive iron ( $Fe^{55}$  and  $Fe^{59}$ ) by feeding isotopic iron to donors, J. G. Gibson et al.<sup>20, 21</sup> were able to show that when blood was drawn as stated above, maintained at 4 to 10°C for twenty-one days and then transfused, 70 to 80 per cent of the transfused cells were viable at least five days after transfusion. To achieve the same survival under comparable conditions, blood in a neutral citrate glucose solution (diluent volume equal to blood volume) could be stored only fifteen days, and blood in sodium citrate could be stored only one to four days.<sup>25</sup> If the temperature rises above 15°C even once during storage, subsequent cooling fails to retard the rapid rate of deterioration thus initiated,<sup>22, 23</sup> though spontaneous hemolysis may not occur before transfusion. With 80 per cent survival, all the nonviable erythrocytes are removed from the circulation within twenty-four hours (most within two hours).<sup>22, 23</sup> All the iron from the nonvital cells is utilized to make new hemoglobin. Utilization is about twenty times that of equivalent amounts of iron given by mouth.

Although some thought a 7:3 blood diluent ratio optimal,<sup>26</sup> the practical aspects of smaller diluent volume led to the development of an improved ACD formula using 75 cc diluent for 500 cc of blood,† and achieving equal preservation. Strumia et al.<sup>31</sup> report the satisfactory routine hospital use of 5000 bottles of blood preserved with this formula.

The same investigators,<sup>21, 26, 30</sup> studying the preservation of erythrocytes discarded from plasma preparation, agreed that the best survival resulted when blood was collected in cooled bottles and immediately separated, and the cells resuspended in ACD solution if collected in sodium citrate, or stored undiluted if collected in ACD and diluted with a little hypertonic saline solution just prior to administration, 80 per cent survival was possible after ten to fifteen days' storage by this method.

\* Acid-citrate-dextrose solution (ACD-1) formula: sodium citrate  $Na_2C_6H_5O_7 \cdot 2H_2O$  — 1.33 gm. per 100 cc. citric acid ( $C_6H_8O_7$ ) — 0.47 gm. per 100 cc. dextrose (anhydrous) — 3.00 gm. per 100 cc. 25 cc. of the solution is used for each 100 cc. of blood.

† The revised formula of ACD-3 is as follows:  $Na_2C_6H_5O_7 \cdot 2H_2O$ , 1.60 gm. per 100 cc.  $C_6H_8O_7$ , 0.56 gm. per 100 cc. and dextrose (anhydrous), 1.50 gm. per 100 cc. 15 cc. of ACD-3 is used for each 100 cc. of blood.

## Use

Whole blood was originally transfused to replace that lost by hemorrhage.<sup>32</sup> It was also found to be effective in traumatic shock even when external blood loss had been minimal. This is to be expected from the currently accepted theories that the shock is a condition of diminished cardiac output depleted circulating blood volume and peripheral vascular collapse.<sup>7, 8, 11</sup> Evidence for and against a humoral or neurogenic origin, or both, is still confusing. Severe shock, however, often fails to respond to massive transfusions, thereby casting some doubt on the theory that deranged circulatory dynamics was the major physiopathology of shock. Seligman et al.<sup>24</sup> have sought to incriminate the liver. Perfusion of the liver by cross circulation with a donor dog (femoral artery to splenic vein) saved 8 of 9 dogs in standardized "irreversible" hemorrhagic shock, whereas femoral-artery to femoral-vein perfusion saved only 2 of 9 controls.

Seeking to make blood more effective, others have tried intra-arterial or intracardiac transfusions. Glasser and Page<sup>25</sup> revived 9 of 35 dogs kept in hemorrhagic shock for two and a quarter hours, then bled until pulse and respiration ceased and finally given intra-arterial blood and artificial respiration. Lefebure,<sup>36</sup> in France, was quite successful with intracardiac infusions of oxygenated blood in shocked cats or oxygenated intracardiac autotransfusions in drowned and electrocuted cats, drawing blood from the femoral vein, oxygenating it and giving it into the heart. He records the rumor that, using this method, Vladimir Negoski in Russia saved 12 of 51 soldiers considered otherwise lost. Iokhveds<sup>37</sup> reports 2 such cases, 1 of which was saved. Kay and Hacker<sup>38</sup> gave oxygenated blood into the ascending aorta and believed that a patient exsanguinated from a stabbed right internal mammary artery was saved thereby.

Two uses of transfusion, apart from shock treatment, have been featured recently. European workers<sup>39</sup> seem to believe that frequent small transfusions hasten convalescence from rheumatoid arthritis faster than the mere replacement of hemoglobin alone. Barsi<sup>40</sup> thinks this particularly effective if the donors are pregnant.

The most spectacular new use for blood has been the substitution therapy for erythroblastotic infants, reported by Wallerstein<sup>41, 42</sup> and others.<sup>43</sup> Since the newborn infant's total blood volume is only 250 cc, it is possible to infuse Rh— blood and withdraw the patient's blood simultaneously from a different vein for sixty minutes, leaving at the end only 36.7 per cent of the infant's blood in its circulation. Alternate removal and replacement of 50 cc of blood five times reduces the residual blood to 32 per cent and the addition of 100 cc of Rh— blood reduces this further to 25 per cent, thereby providing enough blood to live on until all the

circulating Rh agglutinins have been used up. Seven of 9 infants so treated were in satisfactory condition six months later. Wallerstein takes such infants off breast feedings, since Witebsky<sup>44</sup> has shown that it is possible to excrete Rh agglutinins in milk. Cathie,<sup>45</sup> however, denies that this is clinically significant.

Almost all blood is now given indirectly. Only one new device for direct transfusion has been described recently, and it is from Australia.<sup>46</sup>

### Reactions

The usual reactions to transfusions — pyrogenic and hemolytic — are now considerably less frequent owing to more careful preparation of equipment, better crossmatching and the use of more potent grouping serums. Several other types of reactions merit closer attention.

Although *homologous serum hepatitis* is much more common after plasma than blood transfusions, it does occur with the latter. Two fatal cases are reported<sup>47, 48</sup> in infants fifteen to sixteen weeks old who had received three blood transfusions each sixty to one hundred days before, and a fatal case in an adult is reported from Argentina.<sup>49</sup> The most complete follow-up survey yet done included 1050 patients receiving blood or plasma, or both, and 891 receiving blood alone<sup>50</sup>; 73 per cent of the first group and none of the second were considered to have had hepatitis. Nevertheless, no one should be used as a donor who has had jaundice, been exposed to jaundice or received any injections of blood or its derivatives in the preceding six months.

A case of transfusion-induced quartan malaria is reported by Fischer and York<sup>51</sup> from Providence, Rhode Island, occurring in a native, unexposed New Englander receiving three transfusions from donors who had had malaria in early life but had been symptom-free and living outside an endemic area for thirty, thirty-six and forty-two years respectively. These authors report from the literature 12 other cases of transfusion malaria in Massachusetts between 1929 and 1944, 10 of the donors having previously lived in endemic areas, and 5 of these having been symptom-free more than twelve years. The bloods in this case had been stored at 6°C for five, seven and twelve days. Coggeshall<sup>52</sup> also reports transmission from eight-day-old blood. It is important, then, to reject as donors all people who have ever had malaria, and if a would-be donor has lived in an endemic area or taken suppressive therapy, to wait at least two years<sup>52</sup> before use as a donor, and then only if no symptoms have developed. Even this procedure is not entirely safe, for Rogers<sup>53</sup> has recently reported a case of quartan malaria appearing in an eighteen-year-old London girl

eight weeks after receiving one ante-partum transfusion from a donor who had lived five months in a malarious area seven years before but had never shown any clinical symptoms of infection.

An interesting observation on the use of the *universal donor* — Group O — was made during J. G. Gibson's<sup>54</sup> cell-survival studies. A Group A recipient given radioactively tagged O blood had 800 cc of his own blood destroyed by the high anti-A agglutinin content of the donated blood. It was possible to show that the recipient's cells were the ones destroyed because there was no diminution in the number of tagged donated cells. A similar reaction, but with fatal outcome, is reported from England<sup>54</sup> in which a thirty-eight-year-old Group A man with a pistol shot wound received three transfusions of O blood, with severe hemolytic reaction and death from lower-nephron nephrosis. The donors were found to have anti-A agglutinin titers of 1 256, 1 512 and 1 4096. In the Red Cross, Army and Navy whole-blood program, 205,907 bottles of O blood were sent to the European theater and 181,555 bottles to the Pacific.<sup>55</sup> All blood had anti-A and anti-B titrations done, and the 20 per cent with the highest values were reserved for use in O recipients. The remaining 80 per cent had titers well below 1 64. Although a fair amount of pigment nephropathy and lower-nephron nephrosis was seen in North Africa and Italy — Snyder<sup>56</sup> reports 68 fatal cases in Fifth Army Hospitals in 1944-1945 — it was believed that this might well have been due to prolonged shock of severe degree before resuscitation rather than to the O blood. Perhaps this is true, since an analysis of 21,296 reports (part of the 171,564 bottles of O blood administered in the Pacific) failed to show any case with similar lesions.<sup>57</sup> (The total reaction rate in this series was only 3.1 per cent.) If O blood is to be used for universal transfusion, it should have an anti-A and anti-B agglutinin titer of 1 64 or less, or Witebsky's<sup>58</sup> A and B substances\* should be added before transfusion.

The *anuria* following hemolytic transfusion reactions has been treated<sup>59</sup> by the use of the artificial kidneys of Kolff<sup>60, 61</sup> and Murray<sup>62</sup> and the peritoneal irrigation of Frank, Seligman and Fine.<sup>63</sup> It is not yet possible to pass judgment on their effectiveness.

In the best Gallic tradition, Hustin and Rémy<sup>64</sup> studied transfusion-reaction rates in relation to sex. The over-all rate of 9.2 per cent for 864 transfusions given to 425 men and 439 women when broken down showed only 5.3 per cent reactions when donor and recipient were both

\*These are complex carbohydrate like compounds free from protein that seem to play an important part in the composition of isoagglutinogens and combine with isoagglutinins rendering them ineffective. Commercial preparations are obtained from pepsin, mucin, peptone, gastric juice, hog stomach and so forth.

men, and 17.3 per cent when both were women. When all donors were men the rate was 7.2 per cent, and when the sexes were mixed (man to woman or vice versa) the rate remained 7.7 per cent. The authors highly recommended the last procedure.

### *Salvage of Erythrocyte Residues*

Apart from a limited use of erythrocyte transfusions in anemia,<sup>65</sup> valuable for their small volume, little progress has been made toward salvaging the large quantity of erythrocytes accumulating from a plasma or plasma-fractionation program. Early interest in red-cell pastes<sup>66</sup> or dried preparations as stimulants for wound healing has waned and is now reported chiefly from Europe.<sup>67, 68</sup>

Van Slyke and his associates<sup>69-71</sup> have reported their experiences with the preparation and use of dried hemoglobin for transfusions. Following earlier work,<sup>69</sup> they evolved the following method. Cells are laked with distilled water, stroma precipitated by bringing the reaction to pH 5.7, most of the potassium removed by exchanging for the sodium of sodium zeolite, zeolite and stroma removed by centrifuging, physiologic concentration and reaction achieved through the addition of sodium chloride and sodium bicarbonate, and sterility obtained by Seitz filtration. This gives a solution of 95 to 98 per cent hemoglobin in the active form with no conversion to methemoglobin in solutions kept two and a half months at 4°C. If 99.7 per cent deoxygenated, it is readily lyophilized without developing methemoglobin. This material stored in vacuum retains all its oxygen-binding properties for one hundred and eighty days at 4° to 30°C, ninety-two days at 38°C and seven days at 56°C. After restoration in a vacuum, no methemoglobin is formed, and the material can then be kept in solution with impunity.

A 7 per cent hemoglobin solution was quite satisfactory for treating hemorrhagic shock in dogs.<sup>71</sup> A transitory depression in urea clearance in some of the dogs following hemoglobin treatment has led the Van Slyke group to recommend that hemoglobin not be used clinically until the significance of this is clarified. Since most reactions following hemoglobin administration have been shown to be due to methemoglobin<sup>72, 73</sup> and since this preparation contains practically no methemoglobin, stroma or lipids, it is quite possible that a safe, effective hemoglobin solution can soon be prepared.

Strumia et al.<sup>74, 75</sup> sought to avoid the dangers of methemoglobin and perfected a method for the preparation of modified globin. This is a moderately homogeneous preparation with a slightly asymmetric molecule weighing approximately 34,000<sup>74</sup> and having colloidal and nutritional properties quite similar to those of serum albumin. They concluded from studies on 7 surgical patients that globin could replace plasma in supplying protein

needs.<sup>76</sup> The "doubly depleted" dogs (anemic and hypoproteinemic) of Robscheit-Robbins and her co-workers<sup>77</sup> used this human globin to form hemoglobin and plasma proteins though dog globin was better tolerated.

### *Physiology*

The physiologic tagging of erythrocytes through the use of radioactive iron enabled investigators to study the *erythrocyte life cycle* in vivo as well as in vitro. The evidence from transfusion-survival studies<sup>21</sup> of a life cycle of one hundred to one hundred and twenty days (approximately 1 per cent per day disappearance) taken with the earlier results of Ashby and Wearn<sup>78</sup> using nonagglutinable cell technics, and Hawkins and Whipple,<sup>79</sup> who followed hemoglobin excretion, as well as the recent work of London, Shemin and Rittenberg,<sup>80-82</sup> who labeled the globin portion by feeding glycine containing N<sup>15</sup>, leaves little doubt that normal erythrocytes have a life span of one hundred and ten to one hundred and thirty days. It is difficult to understand the results recently reported in Scandinavia<sup>83, 84</sup> of thirty to fifty days (the figures most frequently quoted before the war). Perhaps the reticulocytes and elliptocytes used in these careful studies do not behave as normal adult erythrocytes do.

The *sludged-blood* report released by Knisely's group<sup>85</sup> summarizes their work for the past sixteen years in an important aspect of physiology. They have observed and photographed<sup>86</sup> the circulation of thousands of intact and dissected animals and, using a binocular dissecting microscope and oblique illumination, have studied the corneal and conjunctival vessels of hundreds of normal subjects and patients. They found that in the healthy organism no fluid leaks through capillaries, there is no erythrocyte agglutination or phagocytic removal of red cells, and blood flow is faster in the center of a blood vessel, the cells moving in concentric tubular layers with plasma next to the intima. There are numerous acute bottlenecks at arteriolar-capillary junctions, since the capillaries are only slightly larger than the erythrocyte diameter. The bottlenecks and capillaries are extremely labile and capable of complete self-occlusion. Even during occlusion in normal animals fluid leakage did not occur unless the capillaries were forcibly dilated—in which case the proteins always leaked out. In almost all diseased states (over 600 unanesthetized patients), including mild sinusitis or colds, the leukocytes rolled along and stuck to the blood vessel walls, and many capillaries were dilated and leaking and were packed with erythrocytes stuck to each other quite firmly by a clear tenacious substance. These "sludges" frequently obstructed vessels for hours. Their moving pictures of normal and sludged blood in

color are most instructive and are available for viewing.<sup>87</sup>

### Procurement

At present, whole blood is irreplaceable in modern therapeutics. To guarantee a continued supply in the quantities that came to be used during the war, several agencies have set up peace-time procurement plans. The National Association of Blood Donors in Italy seeks Government recognition.<sup>88</sup> The Ministry of Health in England supplies whole blood and plasma.<sup>89</sup> Besides the state blood and plasma programs of Michigan and New York<sup>90</sup> and the Massachusetts<sup>91</sup> program of whole blood and plasma fractionation, the American Red Cross initiated a nationwide peace-time procurement program in November, 1947.<sup>92</sup> Opening their first center in Rochester, New York, at that time, they hoped to establish twenty to twenty-five more this year, and in three to five years they plan to collect three million donations annually. This is in collaboration with existing state and local facilities and is to provide blood for transfusions, fractionation and research, all free of charge.

### PLASMA

#### *Homologous Serum Hepatitis*

The brilliant wartime career of plasma is now a well known and well documented story.<sup>11, 93</sup> Suggested by Ward<sup>94</sup> in 1918, first used by Filatov<sup>95</sup> in 1935 and reported in this country since 1938, this therapy became very popular with the establishment of plasma and serum programs in Britain and America to meet wartime needs. The details of collection, preservation and use need not be recounted again.<sup>11</sup> Having played an irreplaceable role in war medicine, plasma therapy now faces a serious threat to its future use—the danger of transmission of homologous serum hepatitis or jaundice. First reported in 1937,<sup>96-99</sup> this disease was thought to be of little consequence until, with more general use of plasma, larger pools and more donors, it was observed with increasing frequency in Britain and later in the United States.

The widespread use of plasma, the transient character of military-hospital populations and the long incubation period of the disease have seriously limited attempts to estimate the incidence of hepatitis following blood and plasma transfusions. The most complete survey yet reported is by Spurling, Shone and Vaughan.<sup>50</sup> They followed all patients surviving at least four weeks after receiving serum or plasma in 78 northwest London hospitals from 1940 to July, 1945, all receiving blood from January, 1944, to July, 1945, in 23 of these hospitals, and an equivalent number of controls matched as nearly as possible according to age, sex, ward and hospital but who received neither serum nor plasma. The authors were able to communicate with or study adequately 1054 of the 2040 receiving serum and plasma and 891 of the

1284 receiving blood alone (these patients received 2278 of 2468 bottles given). The serum-plasma group revealed 77 cases suggestive of homologous serum jaundice (7.3 per cent) and 1.3 per cent with jaundice of other origin. None of the blood recipients or the controls had jaundice in five months.

On June 1, 1945, the United States Army conducted a hepatitis survey in all its general hospitals in the United States.<sup>100</sup> Of 1762 patients with jaundice on that day, 500 gave a history of recent transfusions with blood or its derivatives. In the preceding thirty days, 9 of 15 patients dying of jaundice had been transfused previously.

Scheinberg et al.<sup>101</sup> followed 2443 transfusions from the blood bank of the Peter Bent Brigham and Children's hospitals in Boston between August, 1944, and August, 1945, and found 11 cases (0.45 per cent) of hepatitis, including 4 deaths.

Brightman and Korns<sup>102</sup> followed 649 recipients of surplus Army and Red Cross plasma in New York state and found 4.5 per cent hepatitis, with no hepatitis in 1597 household contacts (therefore, it was unlikely that the hepatitis was infectious). In six months 51 deaths from acute hepatitis were reported, 15 of these patients had been previously transfused, 12 with plasma alone.

Rosenthal<sup>103</sup> gave 695 units of blood and plasma to 98 patients in ten months with 4 cases of probable serum hepatitis (none with blood alone).

Grossman and Saward<sup>104</sup> from September, 1943, to September, 1945, had 8 cases of hepatitis (including 1 fatal case) in 501 infusions of commercial liquid plasma. Ginsberg<sup>105</sup> reported a fatal outcome in 2 of 14 cases.

Three cases following the administration of blood alone were discussed above.

A method of *destruction* of the etiologic agent has been reported in only one study. Wolf et al.<sup>106</sup> passed plasma in a thin, rapidly moving film under an Oppenheimer-Levinson source of ultraviolet radiation of 2537 angstrom units and 1849 angstrom units, exposing it for one-third second. They could demonstrate no consistent electrophoretic changes in the plasma and no harmful effects on recipients of it. They failed to present any data on hepatitis-virus survival, merely accepting the earlier work of Oliphant<sup>107</sup> that this amount of irradiation should be virucidal.

Gellis and his associates,<sup>108</sup> however, used 15 human volunteers and demonstrated that heating serum albumin at 60°C for ten hours (routine procedure with salt-poor albumin) actually inactivated known infective virus added to the albumin samples after fractionation.

*Prophylaxis and treatment* with serum gamma globulin (effective for infectious-hepatitis prophylaxis<sup>109-112</sup>) has been quite disappointing. Grossman et al.<sup>113</sup> treated alternate casualties returning to the United States from the European theater

Those treated and controls had received blood or its derivatives. Three hundred and eighty-four patients were given 10 cc of gamma globulin intramuscularly and 10 cc more thirty days later. The incidence of hepatitis among the 384 control patients was 11.5 per cent in the next six months whereas that in the treated group was only 2.9 per cent. Two subsequent investigations unfortunately failed to repeat this. Robinson and his co-workers<sup>114</sup> gave one injection of 10 cc of gamma globulin to 523 Army patients, with resulting hepatitis in 2.1 per cent. The incidence in 449 controls was 2.0 per cent. Duncan et al,<sup>115</sup> in a similar experiment, obtained an incidence of 1.2 per cent in 2406 treated patients and 0.9 per cent in 2374 controls. They observed, however, that Grossman had used two prophylactic injections instead of one, and that in their series the onset of the acute phase was delayed an average of eighteen days among the treated patients who contracted hepatitis.

Besides this difference in response to gamma globulin, Neefe et al<sup>116</sup> with human volunteers and Gauld<sup>117</sup> in a field epidemic of hepatitis in North Africa\* showed that there was no cross-immunization between the two agents. Since there is no cross immunity, since the epidemic virus attacks younger age groups and since the incubation periods vary (infectious twenty-one to forty and serum sixty to one hundred and eighty days<sup>118</sup>) many have sought to explain the survival and transmission of the agent of serum hepatitis, other than by parenteral transfer. Truelove and Hogben<sup>119</sup> suggest the possibility of a sperm-placenta transfer.

In the face of this evidence, the Committee on Blood and Blood Derivatives of the American Red Cross made the following recommendations to the Council on Pharmacy and Chemistry of the American Medical Association<sup>120</sup> that plasma be used only when nothing else is available, that the past history of all jaundice patients be carefully investigated that no blood donors be accepted who have had jaundice or lived with a patient with jaundice or received any parenteral injections of blood or its derivatives in the preceding six months. Until a proved reliable method for inactivating the hepatitis agent is presented, these recommendations should be carried out.

#### Use

Lozner et al<sup>121</sup> report on the safety of liquid plasma stored at room temperature for three years. As a colloidal solution, it is quite satisfactory but electrophoretically shows complete destruction of fibrinogen and gamma globulin and some reduction in beta globulin with a slight increase in osmotic pressure. Destruction of gamma globulins

\*The incidence of epidemic hepatitis in January 1944 among three groups of soldiers was as follows: 438 who had had yellow fever vaccine 11.6 per cent; 7500 who had been vaccinated in 1942 4.5 per cent; 48 per cent and 2500 who had not been vaccinated 4.5 per cent.

and associated antigens gives it an even lower reaction rate than that of dried plasma.

Prober<sup>122</sup> showed that drying to less than 1 per cent moisture made plasma noninfective even when it contained *Treponema pallidum*.

The question of the danger of mercurial preservatives remains unsettled. McNally<sup>123</sup> recommended a maximum of 4 liters of plasma containing mercurial preservatives in a short time to a patient without kidney damage, and less if damage is present. Individual tolerance is quite variable, however, as shown by Leamon's<sup>124</sup> patient who received 437 injections of mercupurin in five and a half years for congestive heart failure and yet showed no kidney damage at autopsy.

Although the use of concentrated plasma has never been too successful, two recent reports are of interest. Cleland<sup>125</sup> successfully treated traumatic pulmonary edema with 400 to 800 cc of triple concentrated plasma. Fearnley<sup>126</sup> kept a patient with subacute hepatic necrosis free from ascites for eight months using 25 units of twice-concentrated plasma.

### PLASMA FRACTIONATION

#### Method

The background, history and development of the plasma-fractionation program have been adequately recorded,<sup>9-12, 127-140</sup> the definitive documentation being now available.<sup>9</sup> Briefly outlined, they are as follows.

Early in World War II, global supply lines and overloaded transportation systems indicated that an effective, stable agent of small bulk for combating shock would be highly desirable, particularly for the Navy. Eventually the Army, Navy, National Research Council, Committee on Medical Research of the Office of Scientific Research and Development, Department of Physical Chemistry, Harvard Medical School, National Institute of Health, Massachusetts Department of Public Health, American Red Cross and seven commercial biologic laboratories collaborated to solve this problem. Until a better substitute was found, it was decided to separate the components of plasma and concentrate the albumin that was chiefly responsible for osmotic pressure, most stable, least antigenic and less viscous. Utilizing differences in solubility dependent on reaction, temperature and salt, protein and precipitant concentrations, Cohn selected ethanol as the precipitant best adapted to commercial use. As Hardy<sup>141</sup> and Melanby<sup>142</sup> had shown in 1905, ethanol does not denature protein at temperatures below 0 to -5°C. It can also be removed and recovered by vacuum drying (lyophilizing).

Originally five groups of more or less similar proteins were separated (Fractions I to V), the last being albumin. Later the second and third groups

were removed together (Fraction II plus III) and subfractionated, Fraction IV was removed in two steps, and a residue, Fraction VI, was left after albumin removal. Details of the method are adequately reviewed by Mulford.<sup>12</sup> Table 1 summarizes the variations in chemical conditions used for separation, and the electrophoretic composition of the principal fractions. Table 2 lists the components of the various fractions with relative amounts and specific interactions. Table 3 gives dimensions of the proteins obtained and of several suggested substitutes. Improved methods have produced at least twenty-seven components, and the old fraction-subfraction nomenclature is losing its usefulness. Plans are underway to re-

foam and thrombin instead of pleura to cover a bronchial stump after lobectomy. Quimby<sup>161</sup> found it to be a useful pack in 40 suprapubic prostatectomies.

There is now considerable literature comparing fibrin foam with oxycellulose<sup>162, 163</sup> and gelatin sponge.<sup>164</sup> Results are essentially the same<sup>165</sup> in neurosurgery,<sup>166, 167</sup> vascular and organ defects,<sup>168</sup> closure of bronchial wounds,<sup>169</sup> obliteration of dead spaces in orthodontics,<sup>160</sup> sinus and mastoid surgery,<sup>161</sup> and nephrostomy<sup>162</sup> and prostatectomy.<sup>164, 161</sup> Buchman and Blair<sup>165</sup> believed, however, that both oxycellulose and gelfoam interfered with the healing of fractures and bone cavities more than fibrin foam did and have abandoned all three for

vise the fractionation method entirely, precipitate the albumin and lipoproteins first, obtain better products and greater yields, designate the components by their chemical names and abandon the Fraction designations.<sup>144</sup> The preparation of so many fractions, with diverse uses, has exceeded in importance the original purpose of fractionation to obtain an agent for combating shock. Each component now has a variety of uses.

### Use of Fractions

**Fibrinogen (Fraction I-2) and Thrombin (Fraction III-2)** These clotting globulins were combined by Bering<sup>145</sup> into a light, sterile absorbable *fibrin foam*, which was originally used as a hemostatic agent in neurosurgery<sup>145, 146</sup> and more recently in other fields. Bailey et al.<sup>147</sup> found it to be an effective agent for stopping oozing and venous bleeding in 240 patients, including hemophiliacs, in whom it caused only slight tissue reaction. It was especially useful in tumor beds and on the cut surface of parenchymatous organs. Fallon and Crookery,<sup>148</sup> in 236 trials, also found fibrin foam valuable in general surgery. It can be employed with penicillin or sulfonamides and in infected cavities,<sup>149</sup> but has no effect on arterial bleeding. Kepl and Ahlquist<sup>150</sup> report the successful use of

dead-space obliteration. This might be due to the high acidity of oxycellulose, which Olwin and Wahl<sup>160</sup> found inactivated thrombin and could not be successfully buffered. The other two did not interfere.

**Fibrin film** prepared by Ferry and Morrison<sup>161</sup> from fibrinogen and thrombin was first used as a dural substitute.<sup>161, 168</sup> More recently it has been used to repair perforations in tympanic membranes and nasal septums.<sup>161</sup> The film has been studied considerably, and its physical characteristics can be altered to provide a "tailor-made" rigid or pliable substance of slow or fast absorption time with minimal tissue reaction.<sup>169-174</sup> Swenson and Gross<sup>175</sup> have utilized this material in the form of rigid tubes for blood-vessel anastomosis with a non-suture technic. With one end of a severed vessel threaded through the tube, that end is then turned back as a cuff over the tube, and this cuffed end is inserted into the other severed blood-vessel end, which is then held in place by a ligature around everything. In 27 dogs whose vena cava or jugular veins were severed and thus reunited all survived, no thromboses occurred, and all evidence of the tubes had disappeared in six or seven weeks. Arteries have also been joined in this manner.

*Fibrinogen and thrombin* injected separately into the renal pelvis, allowed to clot and removed by pelvotomy have brought out all the tiniest stones in 28 of 36 cases reported by Dees<sup>176</sup>

*Fibrinogen* intravenously has been successfully used by Diamond et al<sup>144</sup> to combat congenital hypofibrinogenemia

*Antihemophilic globulin (Fraction I)* The antihemophilic activity of Taylor's unidentified globulin

*Gamma globulin (Fraction II)* Most antibodies are selectively concentrated in this fraction,<sup>181</sup> and it has been used in prophylaxis and modification of measles with considerable success by groups headed by Stokes,<sup>182, 183</sup> Janeway,<sup>135, 184</sup> Rutstein<sup>185</sup> and others<sup>186, 187</sup> The measles antibodies are concentrated about twenty-five times those of pooled adult plasma and if given before the sixth day after exposure will usually prevent (dose 0.08 to 0.1 cc

†When purified chemical components have been separated from fractions they have not been given new fraction numbers. In that case the fraction number refers to the starting material for the separation of the component

‡These components represent but small proportions of the fraction and subfraction and their properties cannot therefore be deduced from those of the concentrates in which they have been separated

§These components have not been tested for since revision of the fractionation process

\*Albumin binds more bilirubin than the bilirubin pigment globulin in Fraction V 1 and more iodine than has been found in Fraction IV-6

has been found in Fractions I, II plus III and IV-1<sup>181-189</sup> Its nature is still unknown, since no electrophoretic or chemical difference can be detected between normal and hemophilic plasma or fractions but it is distinct from fibrinogen persisting after all clotting ability has been destroyed<sup>175</sup> With potent preparations 400 mg of Fraction I in a 20-cc solution given intravenously has controlled hemophilic bleeding especially if used with fibrin foam and thrombin locally. Dutch workers have obtained similar results using a fibrinogen solution prepared by ether precipitation<sup>180</sup>

per pound of body weight) or modify the disease (dose 0.02 to 0.025 cc per pound), giving a permanent protection. Equally satisfying results follow the prophylactic use of gamma globulin in epidemic hepatitis, especially if this substance is administered more than six days before onset of symptoms as shown by the groups of Stokes<sup>109, 110, 183</sup> and Paul.<sup>111</sup> Dosage varies from 10 cc per adult to 0.15 cc per pound of body weight in children. Unfortunately, it seems ineffective against homologous serum hepatitis<sup>111, 115</sup> despite earlier encouraging work<sup>112</sup>

The evidence on this point remains conflicting, however

Ordinary gamma globulin is ineffective against mumps. When prepared from mumps convalescent plasma, it is useful in preventing orchitis in adult males<sup>183, 187</sup>. Although gamma globulin has been reported to protect against chickenpox,<sup>188</sup> controlled studies have not confirmed this.<sup>189</sup>

Tremendous doses (20 to 100 cc intramuscularly) were ineffective in treating 56 poliomyelitis patients in a New York epidemic when compared with 55 alternate controls.<sup>190</sup> The extremely low attack rate of poliomyelitis has prevented any adequate trial of prophylaxis, very large groups would have to be inoculated to provide statistical data.

Adams and Smith<sup>191</sup> divided students at the University of Minnesota into two similar groups on

The possible origin of gamma globulin<sup>196</sup> from lymphocyte cytoplasm regulated by the pituitary-adrenal secretion and adrenal cortical activity has not been definitely established.<sup>197</sup>

**Isoagglutinins (Fraction III-I)** If plasma from Group A and B donors is pooled separately, anti-A and anti-B isoagglutinins of high titer and specificity can be obtained.<sup>198</sup> This, however, provides only small amounts of anti-A because of the low percentage of Group B donors encountered. Melin<sup>199</sup> overcame this difficulty by ingeniously combining blood from "O" and "B" donors in such proportion that the anti-B agglutinin of the "O" plasma is quantitatively removed by the "B" cells, leaving an adequate supply of potent anti-A material. Because the fractionation method concentrates agglutinins five to eight times it has also been

†From x-ray studies indicating that the hemoglobin molecule is a platelet having the approximate dimensions 36 x 64 x 48 angstrom units.

the basis of previous history of colds. The group receiving 6 cc of gamma globulin in October and 4 cc monthly for six months reported 77 colds (10 severe) as opposed to 132 (28 severe) in the controls. This has not been confirmed as yet.

Because of the grave effects on the fetus of maternal rubella in the first trimester as originally reported by Gregg,<sup>192</sup> gamma-globulin prophylaxis should be considered. No satisfactory series has been reported.<sup>183</sup>

All injections of gamma globulin must be given intramuscularly because of the occasional presence of a depressor substance<sup>189</sup> in some preparations. Although marked anticomplementary activity by gamma globulin has been observed in vitro,<sup>193</sup> none has been demonstrated in vivo.<sup>194</sup> A better preparation may result from the work of Deutsch et al.<sup>195</sup> showing that peptic digestion cleaves the gamma globulin molecule without diminishing antibody activity, thus improving absorption and effecting further concentration.

possible to prepare potent anti-Rh typing serum from pools of poorly immunized Rh— persons with a titer too low for ordinary use.<sup>198, 200</sup>

**Iron-binding globulin (Fraction IV-7)** After Holmberg and Laurell's<sup>201</sup> demonstration that serum iron is transported by an iron-binding protein that is normally one third saturated, Schade and Caroline<sup>202</sup> located this activity in Fraction IV-3,4 (later refractionated as IV-7), where it was identified<sup>203, 204</sup> as a  $\beta_1$  pseudoglobulin of 90,000 molecular weight, binding 2 molecules of iron per molecule of globulin (0.38 to 1.25 gamma of Fe<sup>++</sup> per milligram of globulin). Clinical investigation by Wintrobe et al.<sup>205</sup> and Rath and Finch<sup>206</sup> confirmed the ability of this fraction to transport iron. The latter's figures on 20 normal persons and 86 patients check closely with Laurell's<sup>207</sup> results: a normal serum iron-binding capacity of 314 microgm per 100 cc with normal iron content of 102 microgm per 100 cc, compared with Laurell's capacity of 315 microgm per 100 cc, 34 per cent saturated. The capacity

is unaffected by amount of iron intake. In iron-deficiency anemias the serum iron is decreased, and the unsaturated and total binding capacity increased. All decrease in anemias of infection. In hemochromatosis the percentage of saturation rises considerably. Studying 25 newborn infants and their mothers, Laurell<sup>207</sup> was able to show that the iron-binding protein did not pass through the placenta freely whereas the iron did (mothers, serum-iron 80 microgm per 100 cc and total binding capacity 446 microgm per 100 cc, newborn infants serum iron, 146 microgm per 100 cc and total binding capacity, 226 microgm per 100 cc). Apparently, copper is bound in the same fashion by this protein.<sup>204</sup>

**Miscellaneous.** After Szego and Roberts<sup>208</sup> demonstrated that two thirds of the total circulating estrogen in normal, pregnant or gonadotropin-injected cows, rabbits and women was closely associated with a plasma protein fraction, they were able to locate most of this activity in the 75-percent-lipid-containing  $\beta_1$  "X" protein of Fraction III-0.<sup>209</sup> The plasmin that Christensen<sup>210</sup> considers responsible for fibrinolysis\* is found in Fraction III-3. The choline activity of serum occurs in Fraction IV-6.<sup>212</sup>

\*Possible mechanism: plasminogen + streptokinase = plasmin that is inactive as long as neutralized by antiplasmin.<sup>211</sup>

There is no definite statement that it was ever present.

We have to explain the presence of this mass in the left lower abdomen. That location is the graveyard of all gynecologic diagnoses. It is very difficult to make a diagnosis of a lesion in the left lower quadrant because of the presence of the sigmoid. That is where we "come a cropper" so many times. The patient was operated on for dysmenorrhea, and endometriosis was said to have been found. Apparently it was an external form of endometriosis. There is no mention of involvement of the ovary and nothing is said about what was done at the original operation. I do not know whether the tube and ovary were removed and showed evidence of endometriosis.

DR TRACY B. MALLORY: They were not removed. The surgeon reported that there was peritoneal endometriosis but did only a routine appendectomy.

DR PARSONS: There was a family history of tuberculosis. The chest films were normal. To go along with the possibility of tuberculosis of the tube is the fact that at one time the white-cell count was 3000, although it was said to have been associated with the taking of anacin tablets. It is interesting that every now and then one finds a patient who has a leukopenia at the time of her period. Possibly this was associated with the anacin tablets, on the other hand, she may have had a marked fall in the white-cell count at the time of the period. The fact that she had normal chest films does not necessarily rule out tuberculosis of the tube. The thing that is most likely to rule it out is the subsequent operation. The left tube and ovary and a follicular cyst of the right ovary were removed, and no mention of tuberculosis was made at that time. Unilateral tuberculosis is unlikely. Do we have any note of the pathology at the time of the removal of the left tube and ovary at the second operation?

DR MALLORY: In addition to the fibroid and the follicular cyst mentioned there was a ruptured corpus hemorrhagicum, but no endometriosis could be identified. The tube showed no evidence of tuberculosis.

DR PARSONS: That has some bearing on the rest of the picture. There is one other pathologic entity that closely simulates tuberculosis of the tube. Air insufflation was done followed by a salpingogram. In a number of cases in this hospital I have been grossly fooled. Lipiodol injected into the tube and uterus has produced a granulomatous type of lesion within the tube, and when these lesions develop on the outside of the tube they closely simulate tuberculosis. I do not believe one can distinguish it grossly, and it is very difficult for the pathologist to tell whether this lesion is tuberculosis of the tube or whether it is a granuloma associated with foreign-body reaction to the lipiodol. So that is a possibility.

Endometriosis was mentioned at the original operation and the patient was subsequently given testosterone therapy for dysmenorrhea, with partial relief. One would expect no more than partial relief from testosterone with the type of endometriosis that is external. If the testosterone inhibits the pituitary gland and thereby affects the uterine musculature, partial relief from the dysmenorrhea might occur. I assume that is why she was given it.

I think we have been, in the past, a little bit too ready to take out ovaries in association with endometriosis in younger girls. I think it is possible to be more conservative. The endometriosis can be resected out of the ovary and a fair amount of normal tissue left. However, it is difficult to tell grossly whether one is dealing with a corpus hemorrhagicum or a chocolate cyst due to endometriosis. There is one factor about the diagnosis of endometriosis that puzzles me. With endometriosis the tubes are invariably open and yet in the tests for sterility, the air did not pass readily and the lipiodol subsequently given met a block. The record does not say that there was block, it simply says "complete filling," but when the x-ray film was taken twenty-four hours later it failed to show passage of lipiodol in the peritoneal cavity. Three years before when she came into the hospital this tube must have been open. It is not invariable, but in 276 out of 283 cases of endometriosis that Sampson\* has reported, the tubes were open.

I think the adhesions present in the pelvis at the time of the second operation may well be explained by the presence of endometriosis, but again one would expect that to be ovarian. Adhesions do not occur with external implants on the peritoneum as in ovarian endometriosis.

Everything is "rigged" against pregnancy in this patient, and yet that is what I think she had. In the first place, the air insufflation is said to have shown a block in the only tube that she had. After lipiodol injection no droplets were seen in the peritoneal cavity when the film was taken subsequently. Nevertheless, she came in complaining of pain in the lower back, crampy pain in both lower quadrants associated with nausea, and a brownish vaginal discharge. I interpret this as a delayed period. She was said to have had a period that was normal in all respects two days before entry, but it is possible of course that this was not a normal period at all. I would assume death of the ovum within the tube and consequent bleeding, which might closely simulate a normal period. She had had some brownish vaginal discharge and some crampy lower abdominal pain. On examination the cervix was said to be tender on motion, and an ill defined mass could be felt in the right lower quadrant. The left tube and ovary had been removed. One interesting fact is that definite pulsations were felt in the right uterine artery. We do

BENJAMIN CASTLEMAN, M.D., *Associate Editor*

EDITH E. PARRIS, *Assistant Editor*

### CASE 34411

#### PRESENTATION OF CASE

**First admission.** A twenty-eight-year-old married nulliparous housewife entered the hospital complaining of pain in the left lower abdomen.

She had had dysmenorrhea for several years. In the past she had had an appendectomy and uterine suspension, at which time endometriosis was found. There was a family history of tuberculosis, but the patient's chest films were consistently normal. Recently during her periods she had taken large numbers of anacin tablets and on one occasion the white-cell count fell to 3000. Examination revealed a small cervix and a large uterus, which was thought to contain a large fibroid. An operation was performed and a fibroid, 5 by 5 by 4 cm., was removed. Also removed were the left tube and ovary and a follicle cyst of the right ovary. Many adhesions were present in the peritoneal cavity.

**Second admission** (three years later). Following operation the patient was placed on testosterone therapy for severe dysmenorrhea. She had marked but not complete relief. She had extensive studies for sterility. Another fibroid appeared to be grow-

ing in the uterus. Air insufflation at 200 mm. of mercury produced no shoulder pain. Six months before admission a salpingogram showed complete filling of the right tube and of the proximal stump of the left. There was no escape of lipiodol into the peritoneal cavity.

For two and a half weeks before admission the patient complained of pain low in the back and crampy pain in both lower quadrants of the abdomen, associated with some nausea and a brownish vaginal discharge. Her period, which was three weeks late, commenced two days before admission and was normal in all respects. She stated that she had had delayed periods, brown discharge and similar pain with periods before, but the pain had not been quite so severe. There were no gastrointestinal, genitourinary or cardiorespiratory symptoms, or breast changes.

Physical examination revealed slight tenderness deep in the right lower quadrant, and on pelvic examination the cervix was firm, smooth, and somewhat tender on motion. The uterus was enlarged, apparently with a fibroid. There was a tender, ill defined mass in the right vault, and the pulsations of the right uterine artery were noticeably increased.

The temperature was 99.8°F. (Urine was taken for an Aschheim-Zondek test before admission, but the animals died before the reaction could be read.)

The day after admission an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

**DR. LANGDON PARSONS.** One thing that intrigues me is the inaccuracy of pelvic examination at various times. First, the large uterus was thought to contain a large fibroid, at another time the fibroid appeared to be growing in the uterus, then the uterus was enlarged, apparently with a fibroid.

Physical examination disclosed a round area of swelling 10 cm in diameter in the left paravertebral region at the level of the lower part of the thorax. There was considerable tenderness to percussion, with diminution of breath sounds and tactile and vocal fremitus over this area. There was tenderness of the spleen on deep palpation. The liver edge was palpated one fingerbreadth below the costal margin in the epigastrium and was firm and nontender.

The temperature was 100.8°F, the pulse 94, and the respirations 20. The blood pressure was 98 systolic, 65 diastolic.

Examination of the blood revealed a hemoglobin of 9.8 gm and a white-cell count of 16,000, with 88 per cent neutrophils. Urinalysis gave a specific gravity of 1.018 and was negative for sugar, albumin and bile. A tuberculin test in a dilution of 1:10,000 was negative.

X-ray examination showed that the process in the left-lower-lung field had increased somewhat and was considerably larger than it had been originally. It was difficult to be certain whether it was primarily within the lung or pleura, but it seemed more likely that the bulk of the disease was in the lung. There was also soft-tissue thickening along the left paravertebral margin of the lower vertebrae, which was perhaps slightly more than at the time of previous study. The lumbar spine was not definitely abnormal.

An operation was performed on the fifth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR HELEN S. PITTMAN: I understand that the only x-ray film available is the one taken in the Out-Patient Department one week before admission. Is that correct?

DR JAMES J. MCCORT: Yes.

DR PITTMAN: So that we are missing an outside film taken twelve months before admission — said to be normal — and the Out-Patient Department film taken two weeks after, which was reported to show an area of pneumonitis in the posterior basilar segment of the left lower lobe and possibly a small amount of fluid in the left costophrenic sinus. Then we have the next one taken a week before admission. May we see that, Dr. McCort?

DR MCCORT: The area of pneumonitis described is present in the posterior basal segment of the left lower lobe. This segment also shows partial col-

lapse, and the left leaf of the diaphragm is elevated. A small amount of fluid is present in the left costophrenic sinus. The paravertebral thickening may be caused by a small amount of fluid in the left inferoposterior costomediastinal space. Soft-tissue thickening over the left lateral margin of the chest wall can be seen, and the normal, clear-cut outline of the subcutaneous fat line is lost on that side. The lung fields are otherwise clear. The heart and vessels are normal.

DR PITTMAN: The upper edge of the liver is down a little bit, perhaps one fingerbreadth. It does not necessarily indicate increased size, does it?

DR MCCORT: No.

DR PITTMAN: We are missing the first film taken on admission to the Out-Patient Department and the one taken in the house that shows this process reported in the left-lower-lung field to have increased somewhat and to be considerably larger than in the first film. It is difficult to be certain whether the process is primary in the lung or pleura, but more likely it is in the lung. The soft-tissue thickening along the paravertebral margin is perhaps slightly more marked.

I am having trouble discussing this case because I can make only one thing out of it and I think it is dangerous to have only one idea as soon as one reads a protocol. One should, I suppose, always think of a neoplasm. And this time I would think of neoplasm to exclude it. It does not seem to me that this is the history of neoplasm or that the x-ray films suggest any of the common features of neoplasm. And I am throwing neoplasm out now permanently.

The next thing in the history, which I suppose should get a moment of attention, is the story that the pain at the onset was in the right upper quadrant and was "gnawing," although it was unrelated to breathing or eating. A "gnawing" pain always makes one think of ulcer, but I am throwing that out because it seems to me that the idea that the chest process was anything secondary to the stomach is perfectly fantastic. I always remember a case of empyema that I saw many years ago when I was a house officer that was secondary to perforated ulcer, but I cannot make such a diagnosis fit here at all.

Then we come down, it seems to me, to infection. Infection has to be broken down into three groups: tuberculosis, the more common bacterial infections and the nonbacterial infections. This woman apparently had an acute onset. It was in

not know how often such pulsations are felt with ectopic pregnancy. As I say, everything has conspired against pregnancy. The fact that there were no breast changes is against pregnancy. She had had one follicular cyst, which required removal. This could have been another cyst with infarction, but I am inclined to think that it was an ectopic pregnancy.

DR. JOE V. MEIGS: I did the second and third operations. When I operated the first time the tube and ovary on the left side were included in a mass with a large fibroid, which I removed. The consensus at that time was that it was necessary to remove the left tube and ovary as well as the fibroid. I thought that it was endometriosis and took a suspicious area for biopsy, but according to the report that was sent back I was wrong, although I still thought that she had some. She had a good tube and ovary on the right side. Her husband's sperm count was 60,000,000, which Dr. Ingersoll thought was at the lower edge of normal. We would classify such a patient with a fibroid and endometriosis in the low fertility group and would not expect her to become pregnant. When the recent episode developed she thought that she was miscarrying and Dr. Morris, who went to see her, was of the same opinion. We found the uterus enlarged, with many intramural fibroids, and decided to do a hysterectomy.

#### CLINICAL DIAGNOSIS

Endometriosis  
Ectopic pregnancy?

#### DR. PARSONS'S DIAGNOSIS

Ectopic pregnancy

#### ANATOMICAL DIAGNOSES

*Tubal pregnancy*  
Endometriosis of peritoneal surface of uterus

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: The sections from the tube did show recognizable chorionic villi. There was a very marked decidual reaction in the endometrium of the uterus. At the previous operation we failed to find the endometriosis that Dr. Meigs expected,

in spite of the fact that we examined many sections. On this occasion he sent the specimen over with the familiar safety pins in it, and on cutting our sections from those areas we found the endometriosis.

#### CASE 34412

##### PRESENTATION OF CASE

A thirty-four-year-old housewife entered the hospital complaining of pain in the left chest.

Five months prior to admission the patient had had a "cold," with a temperature of 101 and 103°F at night, without chills. The episode was associated with "gnawing" pain in the right upper quadrant, unassociated with eating or breathing and of an intermittent character. She had received penicillin once and sulfadiazine. X-ray films of the chest were reported normal. Two weeks later pain developed in the left upper quadrant, aggravated by deep breathing and associated with a dry morning cough. The pain gradually became more severe and extended to include the left paravertebral area. She was seen in the Out-Patient Department. X-ray examination showed an area of pneumonitis present in the posterior basilar segment of the left lower lobe and possibly a small amount of fluid in the left costophrenic sinus. The remaining lung fields were clear. The heart and vessels appeared normal. A diagnosis of pneumonitis with residual involvement of the left lower lobe was made. About one and a half months before admission another x-ray examination in the Out-Patient Department showed that the left lower lobe was slightly smaller and more dense than on previous examination. The diaphragm was adherent to the chest wall posterolaterally adjacent to this area. There was possibly a small amount of fluid also present. About one week before admission the patient was again seen in the Out-Patient Department. The left-chest pain, which had disappeared some time after the last visit, had recurred, had become continuous, and was of a pleuritic nature. Since the reappearance of pain, she had run a mild fever and had complained of some insomnia because of pain. At this time there was slight swelling in the left paravertebral region. A history of a weight loss of about 15 pounds since the beginning of the illness was elicited.

DR F THOMAS GEPHART At operation this patient obviously had a fluctuant mass over the left lower chest posteriorly, and we had intended to drain the empyema at the same time. However, when we opened the lesion along the lower medial aspect, we encountered an estimated 100 to 200 cc of cloudy pus, which had no unpleasant odor. We examined the cavity and found no areas of denudation of the ribs or any apparent break into the pleural cavity. So we felt that it would be better to pack this loosely and wall it off before sticking a needle into the chest to try to locate further fluid intrapleurally. We took cultures and a small amount of tissue for study.

DR MALLORY Have you anything to add, Dr Miller?

DR CARROLL C MILLER The only thing that I might add is that in operating we were cautious, particularly because of the location next to the vertebral column, thinking that it might possibly represent cold abscess with origin in the spine and that it might entail subsequent orthopedic maneuvers or possibly contamination of the spinal canal during a drainage operation. But we were more or less forced into operating — this lesion suddenly became so much larger and more tender. The patient was put on chemotherapy. I think two days before operation was done, and the chart actually looked better. In considering the chart alone we might have chosen to wait. After we saw the increased size and the tenderness of the process, we went ahead. I would like to make a statement from the therapeutic and diagnostic point of view — namely, to remind any listeners and subsequent readers of the advisability of being prepared to drain such a process immediately after tapping. This is said, not in criticism of the way in which

the case was handled, because no pus was obtained, but so often we find that a diagnostic tap of the chest is done — maybe in the office or in the patient's bed — without preparation for operation. And we subsequently see a fulminating infection of the chest wall, which requires much more surgical treatment than if it had been immediately drained — by "immediately" I mean within a few hours.

DR ROBERT H BROWNING This patient was seen in the Out-Patient Department, and one thing that is not mentioned in the history was that she was acutely tender over the spine, over the ninth, tenth and eleventh thoracic vertebrae. A few days later when I saw her on the wards the tenderness had disappeared. I wonder if there was any evidence to indicate whether the thoracic spine was involved in the process either at operation or subsequently.

DR MALLORY The tissue removed for biopsy showed many clusters of actinomycetes. I cannot tell you the extent of the anatomic involvement, or whether or not there was empyema or splenic or spinal involvement.

DR GEPHART A barium enema and an intravenous pyelogram were normal.

DR MALLORY Is the patient still in the hospital?

DR GEPHART Yes, she is still in the hospital. She has been afebrile and feels much better. The chest-wall cavity is closing down, although it has been open.

DR PITTMAN What are you treating her with?

DR GEPHART We started on penicillin, but after discussing the case with Dr Kane we have taken several cultures and are trying to find out the sensitivity of this particular organism to various chemotherapeutic agents. At the present time we are also treating her with streptomycin.

the chest, and therefore we should think about tuberculosis. Also, the fact that pleural pain was a rather constant feature should make one think about tuberculosis. It seems to me, going back to two weeks after the onset when the pain moved from the right upper quadrant to the left upper quadrant and was aggravated by deep breathing and associated with morning cough, that the pain was pleural — pain of pleural irritation. The tuberculin test at 1:10,000 dilution was negative. There is no history of sputum at any time, and so none was available for examination. I do not believe that tuberculosis needs to be considered any further.

So far as the common bacterial infections in the chest are concerned, this case began with a "cold," which according to our information was associated with fever and I suppose the common things that go with so-called "colds," and then a morning cough. At that time, when she came to the Out-Patient Department, two weeks after the onset, she had what was interpreted as pneumonitis with residual involvement in the left lobe. The initial x-ray film was said to be entirely clear. Did she have a pneumonia that only partially resolved? Did she have an empyema secondary to that pneumonia? I do not believe she did, and that brings me down to the other group of nonbacterial infections. And of that group I thought immediately of actinomycosis, and I cannot get away from it. We think now that one does not have to suck a straw or anything of that sort to introduce actinomyces into the body. They are present about the teeth and in the mouths of healthy people, at least part of the time, and they go down into the chest and start off the process, which I understand usually starts in the bronchi. I do not know anything about that stage of the disease from personal experience — that is just what I read. This woman started with signs of infection, she then developed a cough, having had some pleural pain (granted, before she had anything in the nature of a cough), and when she first appeared for x-ray study, she had a process in the left-lower-lung field and probably in the pleura. That went on for a bit, and then the symptoms subsided, which is perfectly commonplace in a story of an infection with actinomycosis. She then had a recurrence, having meanwhile come in with signs of chronic infection, such as fever, loss of weight, a significant anemia (98 gm of hemoglobin) and a moderate leukocytosis (white-cell count of 16,000), with 88 per cent neutrophils. The

urine was entirely normal. When she came in the process in the chest had increased. She had a round area of swelling, 10 cm in diameter, on the left posteriorly at the level of the lower thoracic region. We know that actinomycosis invades the pleura, we know it invades the chest wall. She had a tender and palpable spleen, actinomycosis also invades the spleen, or one might have a tender area in the region of the spleen. One may have inflammation in the region above or below the diaphragm, with pleural involvement. So although I think she may have had disease in the spleen, I would not be surprised if she failed to show it. The only preoperative diagnosis that I can make is actinomycosis, and my assumption is that the operation performed was a needle biopsy of this area on the back of the chest or possibly exploration of it.

DR JACOB LERMAN: When this patient first came on the ward the striking thing about the physical findings was the swelling of the chest wall. The lower half of the wall posteriorly was swollen, which was a little unusual in the presence of signs of empyema and pneumonitis. It is not mentioned in the record, but a needle was inserted into the chest wall by the resident, who was unable to obtain fluid. On the following day the swelling of the chest wall increased considerably. We assumed that he got into an area of pus. The service thought that it was necessary to rule out the various types of common organisms that infect the pleura following pneumonia, and, in addition, the uncommon types, particularly pneumonia due to Friedländer's bacillus with empyema. We discussed the possibility of mycotic infections of the chest wall, resulting from empyema. Unfortunately, we did not obtain a culture from the needle so that we were unable to settle the problem until operation was performed.

#### CLINICAL DIAGNOSIS

Unresolved pneumonia, with empyema

#### DR PITTMAN'S DIAGNOSIS

Actinomycosis

#### ANATOMICAL DIAGNOSIS

*Actinomycosis of chest wall*

#### PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY: Will you tell us the operative findings, Dr Gephart?

DR F THOMAS GEPHART At operation this patient obviously had a fluctuant mass over the left lower chest posteriorly, and we had intended to drain the empyema at the same time. However, when we opened the lesion along the lower medial aspect, we encountered an estimated 100 to 200 cc of cloudy pus, which had no unpleasant odor. We examined the cavity and found no areas of denudation of the ribs or any apparent break into the pleural cavity. So we felt that it would be better to pack this loosely and wall it off before sticking a needle into the chest to try to locate further fluid intrapleurally. We took cultures and a small amount of tissue for study.

DR MALLORY Have you anything to add, Dr Miller?

DR CARROLL C MILLER The only thing that I might add is that in operating we were cautious, particularly because of the location next to the vertebral column, thinking that it might possibly represent cold abscess with origin in the spine and that it might entail subsequent orthopedic maneuvers or possibly contamination of the spinal canal during a drainage operation. But we were more or less forced into operating — this lesion suddenly became so much larger and more tender. The patient was put on chemotherapy. I think two days before operation was done, and the chart actually looked better. In considering the chart alone we might have chosen to wait. After we saw the increased size and the tenderness of the process, we went ahead. I would like to make a statement from the therapeutic and diagnostic point of view — namely, to remind any listeners and subsequent readers of the advisability of being prepared to drain such a process immediately after tapping. This is said, not in criticism of the way in which

the case was handled, because no pus was obtained, but so often we find that a diagnostic tap of the chest is done — maybe in the office or in the patient's bed — without preparation for operation. And we subsequently see a fulminating infection of the chest wall which requires much more surgical treatment than if it had been immediately drained — by "immediately" I mean within a few hours.

DR ROBERT H BROWNING This patient was seen in the Out-Patient Department and one thing that is not mentioned in the history was that she was acutely tender over the spine over the ninth, tenth and eleventh thoracic vertebrae. A few days later when I saw her on the wards the tenderness had disappeared. I wonder if there was any evidence to indicate whether the thoracic spine was involved in the process either at operation or subsequently.

DR MALLORY The tissue removed for biopsy showed many clusters of actinomycetes. I cannot tell you the extent of the anatomic involvement, or whether or not there was empyema or splenic or spinal involvement.

DR GEPHART A barium enema and an intravenous pyelogram were normal.

DR MALLORY Is the patient still in the hospital?

DR GEPHART Yes, she is still in the hospital. She has been afebrile and feels much better. The chest-wall cavity is closing down, although it has been open.

DR PITTMAN What are you treating her with?

DR GEPHART We started on penicillin, but after discussing the case with Dr Kane we have taken several cultures and are trying to find out the sensitivity of this particular organism to various chemotherapeutic agents. At the present time we are also treating her with streptomycin.

## ELEVENTH HOUR

ON JUNE 20 Dr Paul R. Hawley, speaking before the presidents and other officers of the various state medical associations, warned them that the moment of reckoning was at hand, that the hour was about to strike after which it would be too late for the medical profession in this country to determine its own future course. There is a strong and growing demand for national health insurance on the part of many powerful and resolute groups in the nation, and already the point has been reached "when the medical profession has the choice only of making a reasonable effort to meet the requirements of these large groups of consumers of medical care, or of watching the private practice of medicine in this country being rapidly

strangled by either co-operative or Government medicine. No other alternatives are left."

This was a straightforward declaration by the chief executive officer of the Blue Cross and Blue Shield Commissions reiterating the important decision that faces medicine today. This decision is not whether there shall be effected an equitable distribution of medical care or whether a planned medical economy is desirable, but who shall bring about these changes.

Organized medicine, so-called (a name now changed to the noncommittal term "medical profession," a faint but fetid aroma having developed about the term "organized"), takes its steps always too reluctantly. It is the conservative bulwark of an ancient calling, and slow motion is almost implicit in its design, each year only those compromises with social reform being accepted that might have been considered progressive in the previous decade. Whether tardy approach is an utter necessity is another matter. Large bodies can sometimes move rapidly in the face of impending disaster.

This slowly moving body, however, is in the unfortunate predicament of being harassed by a confusion of committees and leagues and other groups, each, no doubt, completely worthy according to its principles, but whose insistence serves also to obscure the issue and to hide the light. They are the champions of private practice and a reformed status quo—the pillars of professional dignity; they are the advocates of universal and compulsory state medicine; they are, like General Hawley, the agents of a free system of prepaid medical care, delivered on an actuarial basis, which, today, might be considered as the middle lane of the road down which mankind is traveling.

In all justice the statement may be tentatively advanced and might still prove acceptable to a reasonable majority that this country is not yet ready for that compulsion of which there is already too much in the world. It must be remembered however, that a compulsory Government insurance plan received strong support in the deliberations of the Section on Medical Care of the recent National Health Assembly.

The profession of medicine is not on as sure a footing with its public as might be wished, it has

so far done less than it could and than it should have done to ensure reasonably adequate medical care to all the people. It must remember that some of the criticisms directed toward it in this respect are in a sense a basic compliment. They are an acknowledgment that the services of medicine are considered by the people to be equally indispensable with the various accepted public services and, indeed, the very freedoms that are cherished — pure water and sanitation, police and fire protection, education, freedom of speech and of worship and the privilege of representative government.

If the medical profession does not assume active leadership, however, in assuring adequate distribution of its services and that very shortly, its opportunity will be gone. It is the eleventh hour and there are many that still stand idle outside the vineyard.

### INTERNATIONAL HEALTH PROGRAMS

THE World Health Organization, now firmly established as a member agency of the United Nations, held its first World Health Assembly in Geneva in June and July 1948. As a major part of the constructive work of the Assembly, provisional agenda for various international programs were drawn up and approved.

The Committee on Programme placed malaria control first on the list of recommended activities in view of the high prevalence of the disease with hundreds of millions of cases and millions of deaths occurring each year. Next in order came maternal and child health, tuberculosis and venereal diseases. For further activities it was recommended that particular attention should be given to alcoholism, drug addiction and habit-forming drugs, hygiene of seafarers, influenza, nursing, nutrition, rural hygiene and schistosomiasis.

The proposed methods of attack under each major title are divided into specific procedures, the details of which are pertinent to that subject. These consist of a statement of the particular objectives to be sought, the development of a program of study, the provision of suitable assistance to governments and a program of action on the international plane.

So the world makes its slow progress, with men and nations of good will struggling for mutual bene-

fits in the shadow of still stronger destructive forces. As Sisyphus toiling with his stone in Hades could never quite reach the top of the hill, so mankind, constantly frustrated, still lives in constant hope that at some time all men and all nations may bend their efforts toward a common goal.

### COST OF THE COMMON COLD

AN ATTEMPT to arrive at a rough approximation of the cost to the American people of their common colds has been made by the statisticians of the Metropolitan Life Insurance Company,\* who came up with the appalling figure of well over \$1,000,000,000 a year. This figure was obtained by taking into account the data on incidence of the disease among wage earners, students and other special groups, according to the studies of many reliable investigators. The calculations ran somewhat as follows:

The average person suffers at least 2 colds a year or approximately 300 million annually for the entire country. The average duration of the simple cold is five days, giving a total of one and a half billion days of discomfort, decreased efficiency or disability. A conservative estimate of the time lost from work in this country is one day per employee per year, or more than sixty-million days lost in industry from this cause. Even at a low average of \$7 a day, the result in wages alone is more than \$420,000,000 annually.

The amount spent on medical care and drugs for the treatment of colds by the average family is impossible to arrive at, but it was assumed to be about \$10 a year, or a total of about \$400,000,000. No attempt was made to estimate the cost to employers resulting from the loss of production and disrupted routine, but it, too, must reach a considerable figure for the country as a whole.

These calculations led the Metropolitan's statisticians to arrive at the estimate of over \$1,000,000,000 a year as the cost of the common cold to the American people. Although the common cold is generally considered to be a minor illness, they concluded that any disease in which the cost runs to such astronomical figures must be rated high in the list of enemies of the public health.

\*Cost of common cold. *Statist. Bull. Metrof. Life Insur. Co.* 28 (No. 11) 6, 1947.

## LIFE INSURANCE MEDICAL RESEARCH FUND

THE Life Insurance Medical Research Fund, organized in 1945 by a group of United States and Canadian life-insurance companies, with Dr Francis R. Dieuaide as scientific director, has recently issued its third annual report. At the beginning of 1947 the Fund was contributing to the support of fifty-one research programs and nineteen research fellows. During the year this number was materially increased.

Present studies in which the Fund is interested are directed mainly toward the problems of heart disease, so important from the actuarial point of view, and are grouped under five general headings. These include studies on cellular metabolism of the heart and blood vessels, studies of the flow of blood, studies of kidney function and the development of hypertension, studies of the development of arteriosclerosis and studies of the causes of rheumatic fever.

Contributions by the life-insurance companies to research into the causes of premature death represent a sound investment on their part. Their profits are increased by human longevity, and, conversely, favorable results in the attainment of longevity should have their favorable effect on insurance premiums. It must still be borne in mind, however, lest universal longevity be achieved too rapidly, that the breadth of life may be more important than its length.

## MISCELLANY

### MEDICAL DIRECTOR OF LEVER BROTHERS COMPANY

The appointment of Dr. John J. Poutas, assistant medical director and chief of professional services in the New England office of the Veterans Administration, as medical director of Lever Brothers Company, Cambridge, has been announced.

## NOTICES

### SOUTH END MEDICAL CLUB

A meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, on Tuesday, October 19, at 12 noon. Dr. Paul G. Myerson will speak on the subject "New Trends in Psychiatric Treatment."

This meeting will mark the beginning of the twenty-second year for the South End Medical Club. Physicians are cordially invited to attend.

### NEW ENGLAND SOCIETY OF ANESTHESIOLOGISTS

A meeting of the New England Society of Anesthesiologists will be held in the Auditorium of Building A, Boston University School of Medicine, 80 East Concord Street, Boston,

on Monday, October 18, at 8 p.m. The scientific program will be presented by Dr. Donald E. Hale, Cleveland Clinic, Cleveland, Ohio, whose subject will be "Anesthesia for Neurosurgery. Use of hypotension."

Physicians and medical students are invited to attend.

### JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston  
Lecture Hall, 9-10 a.m.

#### MEDICAL CONFERENCE PROGRAM

Friday, October 8 — Metabolic and Therapeutic Problems of Alkalosis. Dr. Charles H. Burnett.  
Wednesday, October 13 — Journal Review.  
Friday, October 15 — Renal Tuberculosis. Dr. Roger C. Graves.  
Wednesday, October 20 — Pediatric Clinicopathological Conference. Drs. James M. Baty and H. E. MacMahon.  
Friday, October 22 — Rice Diet. Some experimental and clinical observations. Dr. William B. Schwartz.  
Wednesday, October 27 — Some Problems in Clinical Cancer Research. Dr. Fred Homburger.  
Friday, October 29 — Some Special Features of Marked Mitral Stenosis. Dr. Edward F. Bland.

On Tuesday and Thursday mornings from 9 to 10 Dr. S. J. Thannhauser will give medical clinics on hospital cases. On the second and third Friday afternoons in October therapeutic conferences will be held from 2 to 4 with round table discussion. Dr. Robert P. McCombs, moderator, the speakers will be Dr. Somers H. Sturgis, whose subject will be "Sterility," and Dr. Fred Homburger, whose subject will be "Chemotherapy of Cancer." On the second and fourth Friday afternoons of each month Dr. Merrill Sosman will conduct x-ray conferences from 4 to 6. On Saturday mornings from 9 to 10 clinics will be given by Dr. William Dameshek. Medical rounds are conducted each weekday except Saturday by members of the staff from 12 to 1.

All exercises are open to the medical profession.

### NEW ENGLAND DIABETES ASSOCIATION

The fall meeting of the New England Diabetes Association will be held in the Cheever Amphitheater of the Boston City Hospital on Wednesday, October 20, at 8:00 p.m.

The speaker of the evening will be Dr. George W. Thorn, whose subject will be "Some Fundamental Endocrine Relations in Diabetes."

After the clinical program there will be an important business meeting of the Association to discuss future policies.

### SOCIETY MEETINGS AND CONFERENCES

#### CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, OCTOBER 14

##### FRIDAY, OCTOBER 15

\*9:00-10:00 a.m. Renal Tuberculosis. Dr. Roger C. Graves. Joseph H. Pratt Diagnostic Hospital.  
\*9:00 a.m.-12:00 p.m. Combined Medical and Surgical Staff Rounds. Peter Bent Brigham Hospital.  
\*12:00 p.m. X-Ray Conference. Margaret Jewett Hall. Mt. Auburn Hospital. Cambridge.

##### MONDAY, OCTOBER 18

\*8:00 p.m. New England Society of Anesthesiologists. Auditorium of Building A. Boston University School of Medicine.

##### TUESDAY, OCTOBER 19

\*12:00 p.m. South End Medical Club. Boston Tuberculosis Association. 554 Columbus Avenue, Boston.  
\*12:15-1:15 p.m. Clinicoradiogenetological Conference. Peter Bent Brigham Hospital.  
\*1:30-2:30 p.m. Pediatric Rounds. Brnham Memorial Hospital for Children. Massachusetts General Hospital.

##### WEDNESDAY, OCTOBER 20

\*9:00-10:00 a.m. Pediatric Clinicopathological Conference. Drs. James M. Baty and H. E. MacMahon. Joseph H. Pratt Diagnostic Hospital.  
\*11:00 a.m.-12:00 p.m. Medical Clinic. Amphitheater. Children's Hospital.  
\*12:00 p.m. Clinicopathological Conference (Children's Hospital). Amphitheater. Peter Bent Brigham Hospital.  
\*2:00-3:00 p.m. Combined Clinic by the Medical Surgical and Orthopedic Services. Amphitheater. Children's Hospital.

\*Open to the medical profession.

## CHARLES B. TOWNS HOSPITAL

Established 1901

### for ALCOHOLISM, NARCOTIC AND BARBITURATE ADDICTIONS exclusively

THE TOWNS TREATMENT is a medical and psychiatric procedure

Withdrawal of narcotics, either opiates or synthetics, is by gradual reduction and specific medication. After 47 years, this treatment is generally accepted as standard. Physicians and psychiatrists in residence. Trained nursing, physio- and hydrotherapy staff.

Patients are assured of complete privacy if desired

Length and cost of treatment are pre-determined

Advantageously situated facing Central Park. Solarium and recreation roof. Excellent cuisine and service.

## DISSEMINATED LUPUS ERYTHEMATOSUS OCCURRING AMONG STUDENT NURSES\*

L. FRED AYVAZIAN, M.D.,\* AND THEODORE L. BADGER, M.D.†

BOSTON

IN the course of a follow-up survey† on a group of 750 nurses who trained at a large municipal hospital between 1932 and 1946,<sup>1</sup> it was found that 3 of these girls had developed and succumbed to disseminated lupus erythematosus. These cases represent 23 per cent of the total mortality among the nurses, the disease being second only to tuberculosis as the major cause of death. The deaths in the entire group have numbered 13, and have been distributed as shown in Table 1.

The occurrence of lupus three times in this group is by itself a curious and unexpected finding, but its interpretation and significance are doubtful. These figures obviously cannot be compared to the causes of death in the general population of this age group and sex, since several artificial factors enter into the selection of this group to distort the pattern. A search for a factor common to the 3 cases, however, brought to light several circumstances that appear to have a direct bearing on the present-day concepts of the pathogenesis and etiology of the disease.

### ETIOLOGY OF DISSEMINATED LUPUS ERYTHEMATOSUS

Since the earliest reviews on the subject there has remained a group, mainly French, Austrian and Scandinavian, who consider the tubercle bacillus as the etiologic agent in lupus. The great volume of clinical and autopsy material, however, lends no support to this concept, and in this country at least it has been virtually discarded.<sup>2</sup>

A second group, consisting mainly of the British, have become convinced that the hemolytic streptococcus is most usually responsible for the disease. The evidence for this concept is reviewed below.

The etiology of lupus is less definitely stated in this country. Ginzler and Fox<sup>3</sup> (1940) state "There is a tendency at present to regard the disease as a peculiar response, in a constitutionally predisposed

person, to a variety of harmful agents." Multiple etiologic factors are in general considered to be instrumental. The varied etiologies postulated assume the form of tissue sensitization to and destruction by various bacteria or toxins, and are in agreement with Bloch's<sup>4</sup> dictum that "the type and course of the allergic reaction are independent of the nature of the antigen, but vary according to the localization of the antibody, that is, according to which organ reacts to the antigen." The streptococcus is again the organism most frequently

TABLE 1 Causes of Death Among 750 Nurses, 1932-1946

CAUSE OF DEATH	NO. OF CASES	PERCENTAGE OF DEATHS
Tuberculosis	4	30.7
Disseminated lupus erythematosus	3	23.0
Staphylococcal septicemia	1	7.7
Carcinoma	1	7.7
Accident and suicide	2	15.4
War casualty	2	15.4

incriminated, with the pneumococcus,<sup>5</sup> staphylococcus and even the gonococcus<sup>6</sup> receiving mention. Among nonbacterial agents, horse serum has received attention, as in the case of lupus described by Fox,<sup>7</sup> in which the disease followed the administration of prophylactic antitetanus serum. Throughout the entire pattern, hypersensitivity and allergy now receive major consideration.

In spite of these various speculations the etiology of lupus has remained unknown. It is of interest, however, to review the accumulating evidence supporting the concept that includes lupus among other diseases thought to be associated with allergy and hypersensitivity.<sup>2, 5-15</sup>

### Allergy or Hypersensitivity

The clinical and pathological features of the syndrome have been compared to the manifestations of serum sickness, and the correlation is frequently extremely suggestive. Indeed, lupus has been claimed by many to represent a prolonged, malignant form of serum sickness.<sup>7</sup>

The pathology of lupus has received critical consideration in several papers, and the findings are

# BACKGROUND

The use of cow's milk, water and carbohydrate mixtures represents the one system of

infant feeding that consistently, for over three decades, has received universal pediatric

recognition. No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri Maltose.

fever and differing from that seen in other sulfonamide reactions. In addition to this observation, it is claimed by Barber as well as others in England<sup>30</sup> and this country<sup>31</sup> that treatment of lupus with the sulfonamides and, later, penicillin has met with dramatic results far superior to any other known therapy, although other reports list such therapy as a failure.<sup>32</sup>

It is further claimed that at least among the cases seen in England streptococcal septicemia is a usual form of death in fatal cases, and that evidence of tuberculosis is usually lacking at autopsy.<sup>29</sup> It is postulated by Barber that disseminated lupus erythematosus represents a nonspecific syndrome capable of being provoked by a variety of bacteria or toxins and that in England this agent is in most cases the hemolytic streptococcus, but that in other vicinities the tubercle bacillus may be of greater significance.

Working with a streptococcus isolated from patients with pemphigus, Welsh<sup>33</sup> was able to demonstrate that the serums from cases of lupus possessed antibodies against the organism. Although antistreptolysin titers are not usually measured in such cases, the titer has been shown to reach significant levels such as 1:640.<sup>34</sup> Denzer and Blumenthal,<sup>35</sup> testing the response to Dick toxin in a case of lupus, found it necessary to raise the dose to 120 units before a positive reaction was obtained. These authors state:

We do not know how to evaluate this finding. Dr Dick has advised us that it is unusual, that there are few people who failed to give a cutaneous reaction with such large doses of toxin.

### CASE REPORTS

All the cases of disseminated lupus in this series began insidiously with bizarre manifestations before the disease became clinically recognizable. Each case terminated fatally, and in each the diagnosis was confirmed at autopsy. In compiling the case summaries we gathered information from hospital records, clinic charts and files of the training-school office, and the final integrated summary appears to form a meaningful chronologic picture.

The first case presents a pattern in accord with the present-day concepts of the etiology of the disease, whereas the second and third cases are less convincing.

**CASE 1** J. S., an 18-year-old Negress, entered the training school in February, 1938. The history and physical examination were not remarkable at that time, and the tuberculin reaction was negative. In the fall of 1938 tests and inoculations were begun as follows: on October 1, 1938, Schick test (positive on October 5), on October 3, Dick test (positive on October 4), on October 10, 0.25 cc. of typhoid-paratyphoid vaccine (local erythema and fever and malaise for 24 hours); on October 17, 0.5 cc. of typhoid-paratyphoid vaccine (local erythema); on October 24, 0.75 cc. of typhoid-paratyphoid vaccine (local erythema), and on October 31, 1 cc. of typhoid-paratyphoid vaccine (local erythema).

On November 14 the patient received her first injection of 200 skin test doses (STD's) of scarlet-fever-streptococcus toxin with no ill results. One week later the second

injection of 2000 STD's was given and was followed by joint pains and fever. She remained in bed for 3 days at that time, but did not report to the health office. No mention of this appeared on her clinic chart. Nine days later she returned and received the third injection of 8000 STD's, after which she developed severe arthralgia in the fingers and knees and a sore throat. She was hospitalized for 5 days, during which a low-grade fever was found. Physical findings showed a red throat and a large area of hyperemia extending from the site of the injection on the left arm down the forearm midway to the wrist. Examination of the blood showed a red-cell count of 4,200,000 with a hemoglobin of 80 per cent, and a white-cell count of 7950. The blood Hinton reaction was negative. The urine was normal. She received aspirin with some improvement and was discharged on December 7, with the diagnosis of "Dick-toxin reaction."

She returned to the clinic on December 12, and her inoculations were continued in lower and more gradually increasing doses so that the series included a total of 10 instead of the usual 7 injections, and the highest amount given was 40,000 STD's rather than 80,000. These were presumably injected into the deltoid regions of both arms, alternating from left to right. Epinephrine usually accompanied these injections, as follows: December 12, 8000 STD; December 19, 12,500 STD (in addition to 0.4 cc. of epinephrine); December 27, 20,000 STD; January 4, 1939, 25,000 STD (in addition to 0.3 cc. of epinephrine); January 9, 32,000 STD (in addition to 0.4 cc. of epinephrine); January 16, 1939, 40,000 STD (in addition to 0.4 cc. of epinephrine); January 23, 1939, 40,000 STD (in addition to 0.4 cc. of epinephrine); January 30, 1 cc. of toxin-antitoxin (for diphtheria); February 6, 1 cc. of toxin-antitoxin; February 13, 1 cc. of toxin-antitoxin in addition to 0.4 cc. of epinephrine; and February 20, Dick test (negative).

The patient was re-admitted to the hospital for 12 days in April, 1939, with swelling and pain of the ankles and toes and tenderness of the joints of both hands, which she said had been constant since the Dick-toxin reactions 5 months earlier. An erythematous area with a pustule was present over the right deltoid, which still represented the site of the Dick-toxin injections. At this time urinalysis showed a +++ test for albumin. Examination of the blood demonstrated a red-cell count of 4,250,000 and a white-cell count of 8200. The blood Hinton reaction was negative. The joint pains subsided on aspirin therapy, and the patient was discharged with the diagnosis of "rheumatic arthritis."

Two weeks later the joint pains returned, and the patient developed chills and fever, sore throat and cough. She was re-admitted for 2 weeks 1 month later, at which time one of four Hinton tests was found to be positive, and heterophil antibodies were present up to a titer of 1:64. During this admission streptococcus vaccine was started in small doses but because of a severe reaction further injections were refused. The diagnoses after this admission were "rheumatoid arthritis and infectious mononucleosis."

During the summer months the joint pains became generalized and persistent, and profound weakness appeared. In September the patient first became aware of a skin eruption over her nose and both cheeks, and the saliva became foul. Examination in the Out-Patient Department in November showed no swelling or redness of the joints. The skin of the cheeks and bridge of the nose was purplish red, mottled and indurated, and some indurated lesions were also found on the upper lip. The lymph nodes were enlarged to visible size in the cervical, supraclavicular, axillary and inguinal regions and were soft and nontender. The spleen was enlarged to percussion and was palpable on deep inspiration. At this time examination of the blood showed a red-cell count of 3,180,000 with a hemoglobin of 67 per cent, and a white-cell count of 3650. The erythrocyte sedimentation rate was 36 mm. per hour. In addition to albumin, the urine showed occasional red blood cells, white blood cells and hyaline and finely granular casts.

Final admission to the hospital was on November 11 at the age of 19. The eruption had spread to include the anterior portion of the chest, and the patient complained of frequent chills and a temperature rising to 102°F. In addition to the anemia and leukopenia laboratory examination revealed three positive blood Hinton reactions and two positive gonococcus complement-fixation tests. Heterophil-antibody agglutinations were negative and tuberculin testing gave a negative result to a dilution of 1:100. On x-ray study

described as being entirely compatible with those of allergic or pathergic inflammation<sup>5, 6, 10, 12, 15</sup>. In particular, the work of Rich,<sup>15</sup> which has recently come to include lupus, lends support to this concept. According to Klemperer et al,<sup>10</sup> the common denominator of the pathology of the disease is the widespread fibrinoid degeneration of collagen, considered also to be the pathology of hypersensitivity and hyperergic inflammation, as in the Arthus phenomenon. The fatal outcome in the disease has been attributed to the pronounced necrotic components of these allergic processes,<sup>6</sup> localized in the experimental Arthus phenomenon but widespread in lupus.

Impressive also is the pathological finding in the kidneys of horses rendered hyperimmune to bacteria for the purpose of developing therapeutic antitoxin, on which typical wire-loop glomerular lesions were found.<sup>5, 11</sup> These lesions, described by Klemperer et al<sup>6</sup> as being a characteristic finding in lupus, have been found in only three situations in disseminated lupus, in eclampsia of pregnancy in the human being and in horses in which bacterial antiserum has been produced by repeated intravenous injections of live bacteria. Although the significance and specificity of this lesion is by no means clear, it is considered to be compatible with that of hyperergic inflammation.

The bizarre manifestations of the disease as it unfolds clinically have given rise to much speculation regarding its etiology. Stokes,<sup>8</sup> in 1932, described the victim of disseminated lupus erythematosus as "first and foremost an allergic person explosively and furiously responsive to his infection with a broken or inhibited leucocytic defense." The peculiarities in the behavior of the patient with lupus have long been noted, and their interpretations have stimulated controversy.

Therapy with certain agents, such as gold salts, x-rays, drugs, skin applications, vaccines and serums, is said to offer hope in some cases, but in others precipitates violent reactions and tragic results.<sup>16-18</sup> The intolerance to sunlight is well known and documented. The tuberculin reaction is most frequently negative in these cases, which may again represent an immunologic imbalance since the patients are almost invariably adult. In some cases reaction to tuberculin administered intracutaneously is explosive, and has been known to be fatal.<sup>19, 20</sup> The Wassermann reaction very frequently becomes positive during activity of the disease without evidence of syphilis being present,<sup>21</sup> again representing abnormal antibody content.

Hyperglobulinemia is a constant occurrence in lupus, as found by Coburn and Moore,<sup>22</sup> and the erythrocyte sedimentation rate rises to levels much higher than those usually seen in infections, achieving the ranges seen in multiple myeloma, lymphopathia venereum and other high globulin syndromes. Electrophoretic analysis of the plasma

fraction showed the gamma globulins to be elevated and the other globulins normal. This pattern is also found in hyperimmune horse serum, apparently representing antibody. The antibody for the Wassermann reaction is apparently also in this electrophoretic area.

Again illustrating the overwhelming antibody response elaborated in the lupus syndrome, Calender et al<sup>23, 24</sup> report their extensive investigation of a patient who received a series of transfusions and developed "a remarkable series of antibodies in her serum." They demonstrated that she had immunized herself against the bloods of eight different donors with the formation of one familiar and three new antibodies, thereby exhibiting an extraordinary sensitivity to antigenic differences with a remarkable liability to undergo isoimmunization.

The occurrence of the disease almost exclusively among female patients between puberty and the menopause appears to bear no relation to the sensitivity state. It is, however, suggested by many isolated observations that a hormonal factor is of some importance in this regard. For example, it has been shown that the Schwartzman phenomenon can most easily be induced in the pregnant laboratory animal.<sup>11</sup> French investigation has demonstrated that the duration of the anaphylactic state can be altered by the removal of the ovaries in the rabbit,<sup>25</sup> and a synergistic effect is suggested. It has been reported that in the occasional male patient developing lupus the urinary excretion of 17-ketosteroids is low, and the follicle-stimulating hormone high,<sup>26</sup> suggesting hypogonadism with increased estrogen-androgen ratio. Premenstrual exacerbation of the disease has been reported,<sup>26</sup> and improvement following natural or induced menopause has also been observed.<sup>26</sup> Treatment designed at reducing ovarian function has met with good results in some hands and failure in others.

### *Streptococcus*

The case for the streptococcus as one of the sources of the antigen in lupus has received consideration in this country as well as in England. This concept apparently gained favor during the early trial of prontosil in various disease states. It was observed by Barber<sup>27-29</sup> that the use of this new chemotherapeutic drug in lupus was followed in 70 per cent of the cases by such reactions as chills, fever, scarlatiniform eruption and a local aggravation of the lesions. In other diseases drug fever and reaction was not seen in greater frequency than 15 per cent. It was believed that the phenomenon in lupus represented a manifestation similar to the Herxheimer reaction in the treatment of syphilis — namely, a general constitutional response to the toxin and bacterial products resulting from a massive bacterial necrosis. The scarlatiniform rash was described as being typical of that of scarlet

fever and differing from that seen in other sulfonamide reactions. In addition to this observation, it is claimed by Barber as well as others in England<sup>30</sup> and this country<sup>31</sup> that treatment of lupus with the sulfonamides and, later, penicillin has met with dramatic results far superior to any other known therapy, although other reports list such therapy as a failure.<sup>32</sup>

It is further claimed that at least among the cases seen in England streptococcal septicemia is a usual form of death in fatal cases, and that evidence of tuberculosis is usually lacking at autopsy.<sup>29</sup> It is postulated by Barber that disseminated lupus erythematosus represents a nonspecific syndrome capable of being provoked by a variety of bacteria or toxins and that in England this agent is in most cases the hemolytic streptococcus, but that in other vicinities the tubercle bacillus may be of greater significance.

Working with a streptococcus isolated from patients with pemphigus, Welsh<sup>33</sup> was able to demonstrate that the serums from cases of lupus possessed antibodies against the organism. Although antistreptolysin titers are not usually measured in such cases, the titer has been shown to reach significant levels such as 1:640.<sup>34</sup> Denzer and Blumenthal,<sup>35</sup> testing the response to Dick toxin in a case of lupus, found it necessary to raise the dose to 120 units before a positive reaction was obtained. These authors state:

We do not know how to evaluate this finding. Dr Dick has advised us that it is unusual, that there are few people who failed to give a cutaneous reaction with such large doses of toxin.

### CASE REPORTS

All the cases of disseminated lupus in this series began insidiously with bizarre manifestations before the disease became clinically recognizable. Each case terminated fatally, and in each the diagnosis was confirmed at autopsy. In compiling the case summaries we gathered information from hospital records, clinic charts and files of the training-school office, and the final integrated summary appears to form a meaningful chronologic picture.

The first case presents a pattern in accord with the present-day concepts of the etiology of the disease, whereas the second and third cases are less convincing.

**CASE 1.** J. S., an 18-year-old Negro, entered the training school in February, 1938. The history and physical examination were not remarkable at that time and the tuberculin reaction was negative. In the fall of 1938 tests and inoculations were begun as follows: on October 1, 1938, Schick test (positive on October 5), on October 3, Dick test (positive on October 4), on October 10, 0.25 cc. of typhoid-paratyphoid vaccine (local erythema and fever and malaise for 24 hours), on October 17, 0.5 cc. of typhoid-paratyphoid vaccine (local erythema), on October 24, 0.75 cc. of typhoid-paratyphoid vaccine (local erythema), and on October 31, 1 cc. of typhoid-paratyphoid vaccine (local erythema). On November 14 the patient received her first injection of 100 skin test doses (STD's) of scarlet-fever-streptococcus toxin with no ill results. One week later the second

injection of 2000 STD's was given and was followed by joint pains and fever. She remained in bed for 3 days at that time, but did not report to the health office. No mention of this appeared on her clinic chart. Nine days later she returned and received the third injection of 8000 STD's, after which she developed severe arthralgia in the fingers and knees and a sore throat. She was hospitalized for 5 days, during which a low-grade fever was found. Physical findings showed a red throat and a large area of hyperemia extending from the site of the injection on the left arm down the forearm midway to the wrist. Examination of the blood showed a red-cell count of 4,200,000 with a hemoglobin of 80 per cent, and a white-cell count of 7950. The blood Hinton reaction was negative. The urine was normal. She received aspirin with some improvement and was discharged on December 7, with the diagnosis of "Dick-toxin reaction."

She returned to the clinic on December 12, and her inoculations were continued in lower and more gradually increasing doses so that the series included a total of 10 instead of the usual 7 injections, and the highest amount given was 40,000 STD's rather than 80,000. These were presumably injected into the deltoid regions of both arms, alternating from left to right. Epinephrine usually accompanied these injections, as follows: December 12, 8000 STD, December 19, 12,500 STD (in addition to 0.4 cc. of epinephrine), December 27, 20,000 STD, January 4, 1939, 25,000 STD (in addition to 0.3 cc. of epinephrine), January 9, 32,000 STD (in addition to 0.4 cc. of epinephrine), January 16, 1939, 40,000 STD (in addition to 0.4 cc. of epinephrine), January 23, 1939, 40,000 STD (in addition to 0.4 cc. of epinephrine), January 30, 1 cc. of toxin-antitoxin (for diptheria), February 6, 1 cc. of toxin-antitoxin, February 13, 1 cc. of toxin-antitoxin in addition to 0.4 cc. of epinephrine, and February 20, Dick test (negative).

The patient was re-admitted to the hospital for 12 days in April, 1939, with swelling and pain of the ankles and toes and tenderness of the joints of both hands, which she said had been constant since the Dick-toxin reactions 5 months earlier. An erythematous area with a pustule was present over the right deltoid, which still represented the site of the Dick-toxin injections. At this time urinalysis showed a +++ test for albumin. Examination of the blood demonstrated a red-cell count of 4,250,000 and a white-cell count of 8200. The blood Hinton reaction was negative. The joint pains subsided on aspirin therapy, and the patient was discharged with the diagnosis of "rheumatic arthritis."

Two weeks later the joint pains returned, and the patient developed chills and fever, sore throat and cough. She was re-admitted for 2 weeks 1 month later, at which time one of four Hinton tests was found to be positive, and heterophil antibodies were present up to a titer of 1:64. During this admission streptococcus vaccine was started in small doses but because of a severe reaction further injections were refused. The diagnoses after this admission were "rheumatoid arthritis and infectious mononucleosis."

During the summer months the joint pains became generalized and persistent, and profound weakness appeared. In September the patient first became aware of a skin eruption over her nose and both cheeks, and the saliva became foul. Examination in the Out-Patient Department in November showed no swelling or redness of the joints. The skin of the cheeks and bridge of the nose was purplish red, mottled and indurated, and some indurated lesions were also found on the upper lip. The lymph nodes were enlarged to visible size in the cervical, supraclavicular, axillary and inguinal regions, and were soft and nontender. The spleen was enlarged to percussion and was palpable on deep inspiration. At this time examination of the blood showed a red-cell count of 3,180,000 with a hemoglobin of 67 per cent, and a white-cell count of 3650. The erythrocyte sedimentation rate was 36 mm. per hour. In addition to albumin, the urine showed occasional red blood cells, white blood cells and bialine and finely granular casts.

Final admission to the hospital was on November 11 at the age of 19. The eruption had spread to include the anterior portion of the chest, and the patient complained of frequent chills and a temperature rising to 102°F. In addition to the anemia and leukopenia laboratory examination revealed three positive blood Hinton reactions and two positive gonococcus complement-fixation tests. Heterophil-antibody agglutinations were negative and tuberculin testing gave a negative result to a dilution of 1:100. On x-ray study

the lung fields remained clear. Clinically, the patient's condition deteriorated rapidly, with a persistently high fever, tachycardia, rising nonprotein nitrogen (to 67 mg per 100 cc) and the development of diarrhea. Petechiae developed terminally, and at this time blood culture was positive for *Staphylococcus aureus*. Electrocardiograms remained normal. The patient finally expired on November 20—1 year after the Dick-toxin reactions and the apparent onset of the disease.

Post-mortem examination confirmed the clinical diagnosis of lupus erythematosus disseminatus. In addition, the coronary arteries were said to show the changes of periarthritis. Other diagnoses were as follows: bilateral bronchopneumonia, mural bacterial endocarditis of the right auricle and ventricle due to *Staph. aureus*, focal abscesses of the myocardium, epicardium, pericardium and endocardium and kidneys.

CASE 2. E. P., an 18-year-old nurse, entered the training school in August, 1939, in good health. Physical examination at that time was negative, and she received the routine inoculations, which are listed in her clinic record as follows: on September 18, 0.25 cc of typhoid-paratyphoid vaccine was followed by local erythema and tenderness; on September 25, 0.5 cc of typhoid-paratyphoid vaccine resulted in a larger and severe local reaction, fever and chills; on October 2, 0.75 cc of typhoid-paratyphoid vaccine resulted in local reaction of the same severity; on October 9, 1 cc of typhoid-paratyphoid vaccine caused a small local reaction; on October 19, Dick and Schick tests were given (both were positive on October 20 and 23); on October 23, 500 STD; on October 30, 1000 STD; on November 6, 2000 STD; on November 13, 8000 STD; on November 20, 25,000 STD; on November 27, 40,000 STD and on December 4, 80,000 STD. scarlet-fever streptococcus toxin were administered\*; on November 13, a tuberculin test was positive; on December 15, 22 and 29, 1 cc of toxin-antitoxin (diphtheria) was given; on January 15 a Dick test was given (it was negative on January 17, 1940); on July 8, a Schick test was given, but the results were not read (the patient was away from school); and on September 6, another Schick test was given (this was negative on September 10).

No record of the patient's health is available until April, 1940, when she was admitted to the hospital for 1 week with chills, fever and headache. The temperature was 104°F, and she was found to have edema of the right orbital tissues and firm cervical lymph nodes. The hemoglobin was 71 per cent, and the white-cell count 7900; the urine was normal. A blood Hinton reaction was doubtful at that time, and an x-ray film of the chest was clear. After return of temperature to normal, she was discharged with the diagnosis of "grippe."

Early in 1940 she began to complain of pains in the feet, numbness of the toes and local erythema, and in May of that year she had plantar calluses excised, although her pains were not localized to these parts.

There is no record of the interval from May, 1940, to January, 1941, when she re-entered the hospital with coryza, cough and sore throat. The right orbit was again found to be inflamed, and the cervical lymph nodes were bilaterally enlarged. Examination of the urine was negative. Examination of the blood showed a hemoglobin of 78 per cent and a white-cell count of 8650. At that time the blood Hinton reaction was positive. She was discharged in 24 hours with the diagnoses of "grippe and conjunctivitis on the right." Because of the doubtful blood Hinton reaction in April, 1940, and the positive reaction in January, 1941, the patient was investigated for syphilis after discharge. She vigorously denied the possibility, and no evidence of the disease could be found. Because of ill health and mental turmoil, however, she finally submitted to a course of antisyphilitic therapy under the care of a private physician. The details of this period are not available.

In February, 1943, after graduation, she re-entered the hospital complaining of a cold with chills of 1 week's duration. The temperature was 105°F.

Physical examination showed an injected throat and a large right cervical lymph node and crepitant rales with bronchovesicular breath sounds at the left base posteriorly.

The urine was normal. Examination of the blood revealed a red-cell count of 3,330,000, with a hemoglobin of 67 per

cent, and a white-cell count varying from 18,100 to 4100. An x-ray film of the chest showed infiltration in the left lower lobe, which improved rapidly on sulfadiazine therapy. She was discharged in 4 days with the diagnoses of "atypical pneumonia and secondary anemia."

Her next admission to the hospital was in June, 1944. She complained of mild pharyngitis followed by pains in the fingers, left knee and right shoulder. She gave a history of pleuritic pain on three occasions 3 months earlier, stating that chest x-ray films taken at that time had been normal. Physical findings included large, nontender lymph nodes in the right cervical region and a systolic murmur at the cardiac apex.

The urine again was normal. Examination of the blood disclosed a red-cell count of 3,400,000, with a hemoglobin of 67 per cent, and a white-cell count between 6200 and 10,650. The erythrocyte sedimentation rate showed marked elevation in all tests. Gastric aspiration was negative for acid-fast organisms. X-ray examination of the lungs was interpreted as showing an area of clouding 1.5 cm in diameter, in the outer zone of the first right interspace, which was considered suspicious of tuberculosis. No bone changes could be identified in the hands. Four electrocardiograms were found to be within normal limits, but PR-interval changes rose to 0.20 second. The infiltration at the right apex cleared, and there was a rise of the hemoglobin to a peak of 75 per cent after liver and iron therapy. She received salicylate therapy and developed a rash. She was discharged in 11 days for rest at home, with a diagnosis of "acute rheumatic fever."

From that time on the patient was aware of a constant fever with occasional bleeding from the gums and palate, weakness and fatigability. She went to Florida in the winter of 1944, and after exposure to the sun she developed and maintained an erythematous, edematous rash over her face, neck and upper back. These areas ulcerated and desquamated over a period of 4 months. The rash gradually faded when she returned to the north, but in the winter of 1945, joint pains returned. In the spring of 1946 she again visited the South and again developed chills, fever, aggravation of the joint pains and return of the rash, which developed a purplish tinge. In July she again entered the hospital for 1 month, presenting a history of chills, with a temperature spiking to 104°F for 3 weeks. There were also severe generalized joint and muscle pains, excessive salivation and loss of head hair. She had been taking large amounts of aspirin since the last hospital discharge, without effect on the pains. Sensitivity to morphine and codeine had developed, with a reaction shown by vomiting and skin rash.

Physical examination in July, 1946, showed a butterfly rash over the face and anterior part of the chest, and a lymph node, 3.0 by 1.5 cm in diameter, in the right cervical region. The heart was enlarged, and a loud systolic apical murmur was described. Urine specimens showed occasional albuminuria, with the tests up to ++. Hemoglobin levels ranged between 27 per cent and 52 per cent, and the red-cell count between 1,400,000 and 1,700,000; the white-cell count was maintained between 3000 and 3900, and the blood Hinton test was positive. Cephalin flocculation was + + + +, and electrocardiograms were normal. X-ray examination of the lungs was negative, but a calcified lymph node was seen in the right cervical region. The temperature ranged to 104°F. Five transfusions of whole blood failed to effect significant improvement.

Final admission was on August 17. Chills, fever and joint pains continued at that time, and alopecia was well developed. Additional laboratory studies showed a rise in the icteric index to 35, a cold agglutinin blood titer of 1:640 and a positive blood Hinton test. Each attempt at blood transfusion brought violent reactions, with chills and temperature reaching over 107°F, so that it became necessary to prepare her for these transfusions with nembutal and epinephrine, as well as warming of the donor's blood. Temperatures remained irregular up to levels of 105°F and the patient finally developed convulsions and disorientation and died on September 4.

The findings at post-mortem examination were described as confirming the clinical diagnosis of lupus erythematosus disseminatus, and no evidence of active tuberculous infection was found.

CASE 3. M. S., an 18-year-old nurse, entered training in February, 1942. Her history at that time revealed that in

\*No statement about reactions to these inoculations was included in the clinic record.

childhood she had had a vesicular skin eruption and one episode of hives while in grammar school. She also reported profuse menstrual flow with severe dysmenorrhea, often associated with nausea and vomiting. Physical examination was negative, as was the tuberculin reaction. She received the following tests and inoculations:

On March 2, 0.5 cc. of typhoid vaccine was followed by a large area of local erythema with discharge. On March 9, 1 cc. of typhoid vaccine was given, and the arm was stiff and painful for 2 days. On March 16, 1 cc. of typhoid vaccine was given. On March 23, Dick and Schick tests were given — they were negative on March 24 and 27, and on March 30, the tuberculin test was negative.

Three months later while at the seashore, she fell asleep on the beach and suffered a severe sunburn. When this subsided it left two small erythematous areas symmetrically placed at the outer end of each eyebrow. These slowly enlarged and spread over the nose and cheeks, preserving a remarkable symmetry. She left the training school at this time, but in September she sought admission to another training school. At that time a "facial acne" was described, and a systolic cardiac murmur was reported over the entire precordium. The Schick test was again negative.

In August, skin lesions had also appeared over the right forearm and over the lumbar spine. By December, the facial lesion had spread around the eye to the cheeks and over the bridge of the nose still preserving symmetry. In January 1943, she developed an upper respiratory infection with diarrhea, for which she was hospitalized for 2 days. Two months later she became aware of profound anorexia and loss of energy. In May diarrhea returned, this time with sore throat and severe headaches. Physical examination showed congestion of the eyelids, nasal mucosa and throat.

Examination of the blood revealed a red-cell count of 2,910,000, with 60 per cent hemoglobin, which fell to 46 per cent in 2 days, and a white-cell count of 27,000. The blood smear showed the presence of small nucleated red blood cells. The urine contained a few red blood cells and white cells per high-power field, and a trace of albumin.

On May 6, she was hospitalized complaining of swelling of the entire face and puffiness of the eyes, fever and sore throat with bleeding from the nose and mouth. There was some cough, associated with substernal pain. Small ulcerated lesions on the fingertips had been noticed for several weeks.

Physical examination showed a temperature of 105.2°F, a pulse of 146 per minute and respirations of 36 per minute. In addition to the eruption symmetrically located over the nose, cheeks, temples and ears, eroded and bleeding lesions were found on the lips, hard palate, fingertips and toes. The face was puffy and swollen and examination of the heart showed a rapid rate with gallop rhythm and a systolic murmur along the left sternal border and base.

Examination of the urine disclosed a ++ test for albumin, and the sediment contained 1 to 10 white cells per high-power field. The red-cell count was 2,980,000, with a hemoglobin of 10 gm., and the white-cell count 4050. The total protein was 5.01 gm per 100 cc., with an albumin-globulin ratio of 2.7:2.3. Throat cultures on two occasions yielded beta-hemolytic streptococci, but the blood culture was negative. Electrocardiograms and x-ray films of the chest were not remarkable.

The temperature ranged between 103 and 105°F, and the patient's course was rapidly downhill. She died on May 9, after an episode of pulmonary edema.

Post-mortem examination confirmed the diagnosis of disseminated lupus erythematosus in addition to bilateral pneumonia and fatty degeneration of the liver.

## DISCUSSION

Considering the current speculations regarding the etiology of lupus, it may be of interest that an allergen can be traced as a possible causative factor in each of the cases presented above. The circumstances preceding the onset of the disease in Case 1 indicate a close association between the reactions to the streptococcus toxin and the disease state itself. Indeed, the metamorphosis from one to the other is such a direct and continuous process that it is impossible to outline the termination of the reactions

to the toxin and the earliest symptoms of the disseminated disease. Although the patient reacted with severe manifestations to the scarlet-fever streptococcus-toxin injections, the entire series was completed. The rash that appeared on her arm at the site of the inoculation persisted for a year up to the time of death, gradually transforming into the lesions of lupus. The facial lesion became a later manifestation. The joint pains and malaise associated with the reactions never fully subsided and slowly merged into the florid process of disseminated lupus.

In Case 2 no such definite correlation could be demonstrated. If, however, the change in the blood Hinton reaction can be accepted as an early serologic alteration of disseminated lupus, it can be seen that this occurred shortly after a series of inoculations had been completed.

In Case 3 the typhoid vaccination might be considered an associated allergen. It was after exposure to sunlight less than three months later, however, that the cutaneous manifestations of lupus first appeared. Fourteen months after the injections the patient died of lupus, having progressed rapidly through the final stages of the disease.

It is conceivable that an antigen was supplied in the form of a bacterial product in all 3 cases, and in 2 it may have been the streptococcal toxin. This is entirely compatible with the multiple or variable nonspecific sensitivity concept of the pathogenesis of lupus as a disease of allergy or adaptation.

The local and systemic reactions to the Dick toxin may be severe in 10 to 15 per cent of cases.<sup>36</sup> These are characterized by headache, fever, nausea, vomiting, abdominal distress, sore throat and scarlatinal rashes.<sup>36-38</sup> Local reactions of purplish mottled and dusky-red erythematous areas<sup>39</sup> which may achieve some chronicity at times, have been described. Muscle and joint pains are apparently less frequently seen, but according to Healer<sup>40</sup> occur in about 3 per cent of young adults immunized. He demonstrated that the arthralgia in 5 subjects was not produced by the protein contained in the broth used in the preparation of the toxin and that it was absent when the toxin was destroyed by heat. According to Toomer<sup>38</sup> the person reacting with arthritis is "never desensitized by repeated injections of scarlet fever toxin to the point where he may not have reactions following subsequent increased injections of the toxin."

If such reactions possess a denominator in common with the so-called diseases of allergy and hypersensitivity, it seems possible that there is a point at which the systemic effect of the antigen-antibody reaction becomes irreversible and the disease progresses even if the antigen is removed. Although the situation outlined above is unusual and artificial, it is conceivable that in other cases a constantly present or frequently recurring obscure infection can render the patient sensitive and from that point on supply a bacterial antigen to initiate a series of bodily reac-

tions similar to those supplied by the injections in these 3 cases

The facts of the cases as presented herein obviously justify no conclusion regarding the etiology of disseminated lupus erythematosus. Can there be an association between the pathogenesis of the disease and allergenic factors?

### SUMMARY

The etiologic speculations regarding disseminated lupus erythematosus as listed in the literature are reviewed. There is a trend at present to include this disease among others thought to be associated with allergy and hypersensitivity, although the evidence for this is indirect.

Three cases of disseminated lupus occurring among student nurses are presented. In 1 the apparent onset of the process coincided with Dick toxin reactions. In the others such a direct correlation was not present, but the disease followed similar inoculations by several months.

The possibility that an allergen was present in each of these cases is suggested.

## NECROTIC LESIONS OF THE LEG IN ARTERIOSCLEROSIS\*

EDWARD A. EDWARDS, M.D. †

BOSTON

IT IS commonly known that necrosis can occur in the toes or feet in the presence of arteriosclerosis. It is the purpose of this paper to indicate that necrosis may likewise start more proximally in the leg, and that the lesion is of grave import and deserves painstaking treatment. The disorder may arise spontaneously as an infarction of the skin and subcutaneous tissue. In other cases the necrosis follows local trauma or infection.

## CLINICAL VARIETIES

*Infarction of the Skin*

In this category may be placed cases in which there is the sudden appearance of a blue-red area on the leg, which quickly turns black. This is followed in a few days by sloughing and ulceration. The limb shows evidence of high-grade arteriosclerosis, with ischemia of long standing. Such lesions are presumably the result of spontaneous thrombosis in small arteriosclerotic arteries, though the exact mode of genesis is not proved. Small lesions of this type resemble those described by Hines and Farber<sup>1</sup> as "hypertensive-ischemic" ulcers. These writers believe that the local ischemia is due to the arteriosclerosis of hypertension. The mechanism of the necrosis is probably the same as that responsible for many such lesions in the toes. Skin necrosis due to local arterial thrombosis is rare, but may be seen in other parts of the body, such as the trunk and the upper extremities.

The infarct and resultant ulceration may be small or large, single or multiple. Its course is to some extent related to the size of the necrotic zone and the location. Small ulcers tend to heal, the larger ones, with the aid of superimposed infection, tend to go on to massive gangrene. A proximal level is somewhat more conducive to healing than a more distal one.

The following cases are representative of those in this group.

**CASE 1** H. R., a 74-year-old man, was seen at the Massachusetts Soldiers' Hospital. He presented three ulcers of the left upper leg of 4 weeks' duration. The lesions had first appeared as painful isolated red spots, which had turned black in 2 days, and had then begun to ulcerate. There was a history of claudication of 10 years' duration, but with no apparent recent change in circulatory status.

Physical examination disclosed three separate ulcers, each about 1.5 cm in diameter (Fig. 1). The edges were irregular with gray sloughing sides and base and the lesion was surrounded by a narrow red areola. The limb was moderately

ischemic. The femoral pulsation was of fair quality, but there was no pulsation below this level. The vascular status of the right limb was similar to that of the involved side.

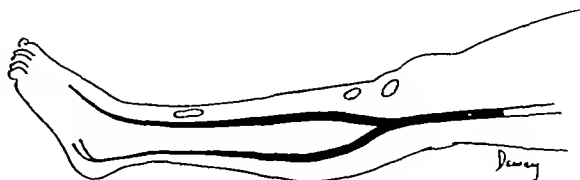

FIGURE 1 Spontaneous Small Areas of Necrosis in Case 1. There is occlusion of the popliteal and both tibial arteries.

The blood pressure in the arm was 160/110. There were signs of arteriosclerotic heart disease, but no overt failure.

Treatment consisted of the daily application of wet dressings of tyrothricin solution (0.5 mg per cubic centimeter). The ulcers improved rapidly and healed in 4 weeks.

**CASE 2** E. LeP., a 57-year-old man, was seen at the Massachusetts Soldiers' Hospital for ulceration of the leg of 2 weeks' duration. The involved area had initially turned black and painful and had then broken down. Diabetes was known to have been present for 6 years. It was well controlled by diet and the taking of 15 units of protamine insulin daily.

Physical examination disclosed a slough, 4 cm in diameter, over the lower lateral aspect of the left leg (Fig. 2). There

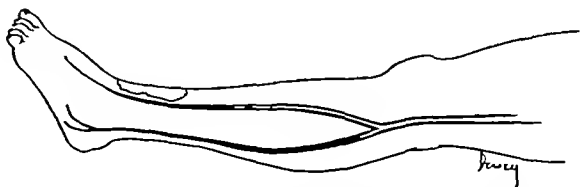

FIGURE 2 Extensive Spontaneous Ulceration in Case 2. There are patent popliteal, narrowed anterior tibial and occluded posterior tibial arteries.

was evidence of mild infection about the involved area. Pulsations of good quality were felt over the femoral and popliteal areas. There was a faintly perceptible pulsation in the dorsalis pedis artery but none in the posterior tibial artery. Oscillometric examination disclosed moderate reduction in pulse expansion and pressure in the upper calf, but great reduction at the level of the ankle. The foot blanched moderately on elevation. The right lower leg showed a similar vascular status.

Treatment consisted of local dressings of tyrothricin solution and parenteral administration of penicillin. The slough had not separated after 6 weeks of this treatment, and infection about the edges of the ulcer was increasing. A lumbar sympathectomy was advised but refused until 5 weeks later. Sympathectomy was performed and induced a marked increase in blood flow. The slough separated in a week, and the ulcer healed 3 weeks after the operation.

\*From the Department of Surgery, Tufts College Medical School. This study was aided by a grant from the Charlton Research Fund, Tufts College Medical School.

†Instructor in surgery, Tufts College Medical School; clinical associate in anatomy, Harvard Medical School; consultant in peripheral vascular disease, Joseph H. Pratt Diagnostic Hospital.

**CASE 3** A. H. P., a 77-year-old man, was referred by Dr. Tracey Roberson, of Ware, Massachusetts, for extensive necrosis of the right leg. Ten days earlier a painful, small, black area had appeared on the lateral aspect of the lower third of the leg. It had increased rapidly in size and appeared to be progressing. Varicose veins had been present for many years, but had not given rise to symptoms. The patient had had a severe coronary thrombosis 7 years and a cerebral vascular accident 2 years before the present illness.

Physical examination showed a black, necrotic zone of irregular outline, 100 by 85 cm, at the junction of the middle and lower thirds of the right leg, mainly on the lateral surface, but encircling about two thirds of the circumference of the leg (Fig. 3). About the ulcer was a red zone of irregu-

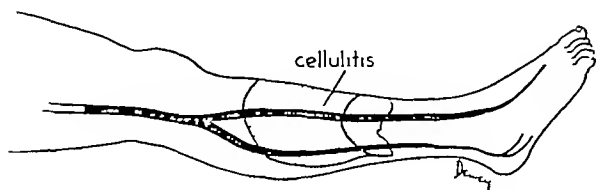

FIGURE 3 Extensive Spontaneous Ulceration with Secondary Infection in Case 3

There is old occlusion of the popliteal and both tibial arteries

lar outline, but no great tenderness or swelling. The foot was cold and dry. There was pronounced blanching on elevation. The femoral pulsation was of good quality, but no pulsation was made out below this level. The oscillometer showed a minimal pulsation below the knee, with no pulsation whatsoever at the ankle. There were a few varices in the calf. The vascular status of the left limb was similar to that of the right.

After a few days' observation it was evident that the ulceration was deep and that infection presented a real threat. Amputation was advised. The patient refused, went home and died from spreading sepsis in 6 weeks.

#### Necrosis Secondary to Trauma or Infection

As in the spontaneous variety, the necrosis following local injury or infection resembles that commonly seen in the toes. The precipitating incident does not need to be severe to set off an advancing necrosis in an arteriosclerotic limb.

Varicose ulcer affords the commonest example of superficial infection of the leg in arteriosclerotic patients. The tissues withstand this chronic form of infection rather well. The ulcers may commonly exist intermittently for many years in the presence of arteriosclerosis without giving rise to gangrene. The lesions will usually heal if the varices are treated by ordinary means. However, one should avoid operative procedures in the lower parts of the leg.<sup>2</sup> Rarely, as in Case 4, necrosis advances outward from a varicose ulcer. The precipitation of the necrosis apparently depends upon a superimposed trauma, an episode of acute varicose thrombophlebitis, the acquisition of a more virulent bacterial flora or further degradation of the arteries by advancing atherosclerosis or arterial thrombosis.

It is important to recognize that trauma and infection can, by themselves, initiate arterial thrombosis (as in Case 6). This reduces further the

limited blood supply, and the necrosis of the limb can extend more easily.

**CASE 4** R. F., a 74-year-old woman, was referred by Dr. Maurice W. Tolman, of Boston. The patient had had varicose veins for about 40 years and varicose ulcers intermittently for 15 years. After having been healed for some months, the ulceration of the right leg had recurred 4 months before the present observations. It was more painful than usual and had enlarged progressively. For 1 month there had been much pain in the calf and foot, and during the past 5 days the foot had become pale and cyanotic.

Physical examination showed multiple foul-smelling ulcerations in the lower two thirds of the right leg (Fig. 4). The deeper parts of the ulcers totaled about 90 square cm. Here the skin and subcutaneous tissues were black and surrounded by additional superficial ulceration. Culture of the ulcers showed hemolytic *Staphylococcus aureus* predominating, with *Staph. albus*, anhemolytic streptococci, diphtheroids and rare coliform bacteria. The small veins in the dorsum of the foot were prominent, and some did not empty after elevation. Several other areas of static blood pigment were

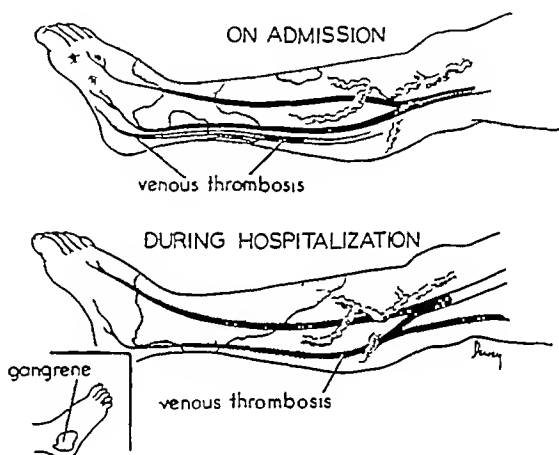

FIGURE 4 Necrosis Extending from Varicose Ulceration in Case 4

On admission there is old occlusion of the popliteal and both tibial arteries and early, deep venous thrombosis and blood pigment in the tissues of the dorsum of the foot. During hospitalization, there is extension of necrosis, extension of venous thrombosis and gangrene of the heel.

seen on the dorsum. The foot and toes showed a general cyanotic tinge, which slowly changed to a blanching after elevation. There was deep tenderness of the foot and calf. No pulsation was made out below the femoral level. The oscillometer likewise revealed no pulse expansion from the upper calf down.

It was apparent that the necrosis of this ischemic limb was complicated by spreading sepsis and deep venous thrombosis of the leg and foot. Thrombosis was also suspected in the finer skin vessels of the dorsum of the foot, and in the deep arteries of the leg and foot.

The patient was given penicillin and sulfadiazine, as well as heparin in Pitkin's menstruum. Dicumarol was soon substituted for the heparin. Wet dressings of tyrothricin solution were applied to the leg. The superficial ulcerations showed a tendency to heal, but it became evident that the slough had extended to the deep fascia in several places. In spite of the chemotherapy, intermittent fever continued. A large zone of gangrene appeared on the heel.

A low thigh amputation was advised and performed. The femoral vein was free of thrombus but there was thrombosis in a large vein in the posterior compartment of the thigh. Microscopical examination showed capillary thrombosis in the superficial tissues of the ulcer (Fig. 5).<sup>3</sup> The popliteal

<sup>3</sup>In my opinion such thrombosis may extend to the veins of the extremity inducing extensive thrombophlebitis.

artery was almost completely occluded, mainly by extensive atheroma, with further narrowing due to hemorrhage within the atheroma. The popliteal vein showed thrombosis. Unfortunately, sections were not made of the vessels of the leg or foot, leaving unproved the clinical impression of thrombosis in the arteries and veins of these parts.

Dicumarol was given postoperatively, but the prothrombin time was not consistently maintained at low levels. The

FIGURE 5 Tissues in Case 4

The upper photomicrograph of the edge of ulceration shows extensive purulent inflammation, with thrombosis of the small vessels in the ulcer bed and extensive proliferative phlebitis without thrombosis in a subcutaneous vein (hematoxylin and eosin stain,  $\times 50$ ). The lower photomicrograph shows the popliteal vessels. The vein on the right shows a completely occluding thrombus. The artery on the left shows extensive atheroma, the narrowed lumen being further reduced by hemorrhage within the atheroma at H (Verhoeff's elastic tissue stain,  $\times 15$ ).

stump and the buttock swelled considerably, suggesting an upward progression of the thrombosis to the common iliac vein. A small slough of the wound edges occurred and required 8 weeks to heal.

After discharge from the hospital, the patient complained of severe phantom pain. On three occasions a deep abscess formed in the stump end and drained spontaneously through

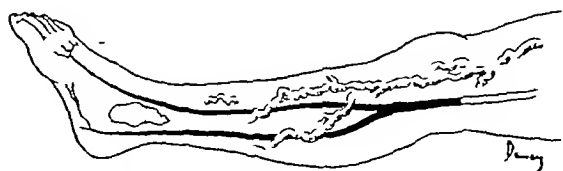

FIGURE 6 Necrosis Following Trauma in Case 5

There is old occlusion of the popliteal and both tibial arteries. Arteries are present.

the scar. A roentgenogram will be taken to determine whether osteomyelitis of the femur is present.

CASE 5 J McC, a 58-year-old man, was seen at the Avascular Clinic of the Boston Dispensary for an ulcer of the right lower leg. Four weeks earlier he had bruised this

area on a hand truck, and the ulcer had formed in a few days. Varicose veins had been present for 5 years, dating back to a deep thrombophlebitis after compound fracture of the leg. Ulceration had never previously been present.

Physical examination showed an ulcer, 4 cm in diameter, on the medial surface of the right lower leg (Fig 6). It was surrounded by a wide inflammatory zone. Beyond the involved area, the skin was atrophic, dry and shiny. The foot blanched markedly on elevation. The femoral pulsations were of good quality, but there were no pulsations below this level. The oscillogram showed a barely perceptible pulse expansion from the upper calf downward. Large varices were present.

A right lumbar sympathectomy and a division of the saphenous vein in the groin were carried out. The ulcer showed immediate improvement but required 3 months to heal. During most of this time, however, the patient was ambulatory and at work.

CASE 6 E W, a 74-year-old woman, was referred by Dr. Paul Hecht, of Braintree, Massachusetts, for ulceration of the right leg. One week earlier, while working in her garden, she had been stung on the leg by an insect. A virulent cellulitis developed, involving the entire leg and associated with chills and high fever. The patient was extremely ill, but improved after large doses of penicillin and sulfadiazine given

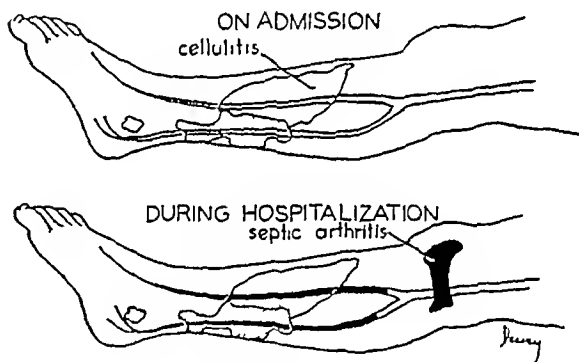

FIGURE 7 Necrosis and Secondary Arterial Thrombosis Following Infection in Case 6

On admission, the major arteries were patent. During hospitalization, thrombosis developed in the tibial arteries, and the knee joint became infected.

orally. Extensive slough of the skin developed, and it was evident that the cellulitis was continuing deeply, though its superficial spread had been halted.

Physical examination disclosed the patient to be in good general condition. Extensive deep slough and cellulitis were present on the medial surface of the right leg, in areas from the ankle to the knee (Fig 7). The dorsalis pedis and posterior tibial pulsations were present and only slightly reduced in volume. The foot showed no evidence of diminished blood flow. Culture of the lesion showed *Bacillus subtilis* predominating, with a hemolytic *Staph aureus* and a nonhemolytic *Staph albus*.

It was hoped that with increased doses of sulfadiazine and parenterally administered penicillin, ultimate separation of the slough and a satisfactory base for skin graft might be obtained. In spite of adequate chemotherapy a low fever continued. On the 5th day, after hospitalization the knee joint appeared distended with fluid, though not tender. The pedal pulses were no longer palpable, and the foot was ischemic.

Amputation was advised and performed above the femoral condyles. The popliteal artery and vein were patent. The knee joint was found distended with pus, and the ampu-

tation was therefore left open. Five days later a secondary suture was done. Healing was satisfactory.

Microscopical examination showed extensive arteriosclerosis in the popliteal, anterior and posterior tibial and in the peroneal arteries (Fig. 8). It was confirmed that acute

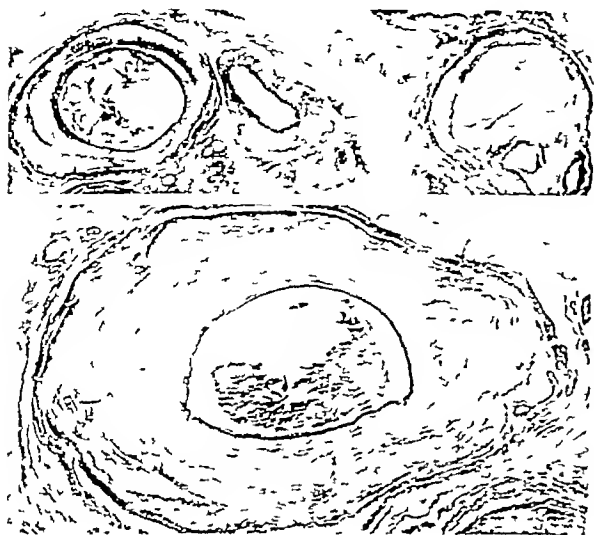

FIGURE 8 *Tissues in Case 6*

The upper photomicrograph of the posterior tibial artery on the left shows atherosclerosis with acute thrombosis, and the peroneal artery on the right is occluded by an old atheroma (Verhoeff's elastic tissue stain,  $\times 20$ ). The lower photomicrograph of the anterior tibial artery shows extensive atherosclerosis with acute thrombosis (Verhoeff's elastic tissue stain,  $\times 50$ ). In both sections the apparent incompleteness of thrombosis is due to an artifact.

thrombosis had taken place in the anterior and posterior tibial arteries.

### CLINICAL MANAGEMENT

In many respects the management of patients with necrosis is the same whether the lesion is located on the leg or on more distal parts. It is clear that the presence of infection and thrombosis must be kept in mind constantly. The advanced age of the patient and the presence of marked arteriosclerosis favor these pathologic processes. The tissues limit infection poorly, so that cellulitis and extension of the necrosis are common, and septicemia is a constant threat.

Thrombosis is encountered in a variety of vessels. Microscopical examination of the necrotic areas often reveals red agglutination thrombi in the surface capillaries. These may sometimes be followed into the subcutaneous veins and arteries. The process is often purulent and suggests a basis for septicemia. Thrombosis of the large deep veins is common, as noted by Veal<sup>3</sup> in gangrene from any cause. This process is usually bland at the popliteal level and aids in limiting the purulent phlebitis of the finer vessels. Organization is slowed in old age, especially in the presence of ischemia. Pul-

monary embolism may therefore be expected with unusual frequency. Thrombosis of the major arteries may likewise occur in the course of the illness, further limiting blood flow.

Except for small spontaneous ulcerations, necrosis of the leg in the presence of arteriosclerosis calls for treatment in a hospital. If ischemia is pronounced, and the necrosis is widespread and deep, immediate amputation appears most logical. Acute spreading infection is likewise an indication for amputation, but an attempt should first be made to control the infection by appropriate and intensive chemotherapy.

One of three types of amputation may be used: guillotine amputation at a low level followed by definitive closed amputation in the thigh, immediate amputation at the high level but with delayed suture, and high amputation with primary suture. Division of both femoral veins should accompany the amputation. My preference is for a division above the termination of the deep femoral vein, but below the circumflex femoral veins.<sup>4</sup> Dicumarol may be given instead, but only if the amputation wound is closed.

Conservative management may be chosen in the hope that the necrosis has not extended deeply, and that the infection will prove controllable. General chemotherapy is of prime importance. Local applications should be bland. In my experience, wet dressings are superior to greasy ones. Tyrothricin solution (0.5 mg. per cubic centimeter) appears to have some advantage over other materials. If venous thrombosis is present, a bilateral division of the femoral veins should be done. If thrombosis is not evident, dicumarol or heparin should be given as prophylaxis.

An increase in blood flow by lumbar sympathectomy may be extremely helpful, but the operation is only occasionally applicable. Sympathectomy should be considered only if there appears to be a good chance of saving the leg. A favorable effect may not be obtained in the very old patient with extensive arteriosclerosis. As a general rule, a good skin-temperature response after spinal anesthesia should be obtained before sympathectomy is performed in patients over fifty-five. This rule should be abrogated if the limb is in jeopardy.

Varices should be treated by high division of the saphenous vein.

In favorable cases these conservative measures may induce healing of the necrotic area. In others, a granulating area may be obtained, which can be skin-grafted, preferably with "pin-point" grafts. It is conceivable that débridement of the necrotic area may occasionally be used as a preliminary to skin grafting.

An opinion regarding the probable outcome of the conservative treatment should be made as soon as possible, generally in seven to ten days. Conservative treatment should be abandoned, and ampu-

tation performed, if it is evident that infection cannot otherwise be controlled, or if the necrosis increases

### CONCLUSIONS

Necrotic lesions on the leg in the presence of arteriosclerosis carry the same possibilities of loss of the limb, or of death, as lesions on the toes or foot

The patients are usually advanced in age, and the arteriosclerosis is severe

The lesions may arise spontaneously from thrombosis of arteries supplying the skin, with resultant infarction. In others, necrosis follows trauma or infection of the leg

The prognosis is poor because of infection and secondary thrombosis—the infection is apt to be difficult to control, and the thrombosis, which is extremely common, involves fine cutaneous and subcutaneous vessels in the necrotic area, the deep veins and occasionally the major arteries of the leg

Amputation is necessary for extensive necrosis, infection incompletely controlled or new areas of necrosis

Conservative treatment may be tried, but should be abandoned unless a good response is obtained promptly. Adequate and appropriate chemotherapy is necessary. Prophylactic use of anticoagulants may be indicated. Venous thrombosis calls for division of the femoral veins or for anticoagulant therapy. Lumbar sympathectomy is occasionally helpful in obtaining healing.

## ANION EXCHANGE RESINS IN THE TREATMENT OF HEARTBURN DURING PREGNANCY

S. CHARLES KASDON, M.D.\*

BOSTON

**H** EARTBURN during pregnancy, an annoying symptom with little if any significance in mortality or serious morbidity statistics, is nevertheless distressing to the patient who suffers from it and to the physician who bears the brunt of the complaints. Rodway and Shelley<sup>1</sup> reported this symptom in 66 out of 100 pregnant women, and the experience of most obstetricians tends to corroborate this incidence. The modern theory for the etiology of heartburn states that the regurgitation of gastric contents into the distal esophagus distends the sensitive neural endings of the esophagus. The distention is further enhanced by intermittent spasm of the cardiac sphincter and causes the symptom. Prostagmin has been administered in accordance with this theory of etiology and has afforded satisfactory relief from pyrosis during pregnancy.<sup>2-4</sup> It is rational therapy since prostagmin has been shown clinically and experimentally to increase isoperistaltic contractions in the gastrointestinal tract.<sup>5-7</sup> It is somewhat disconcerting, therefore, to find that anion exchange resins,<sup>†</sup> admittedly an empiric, unphysiologic therapeutic agent for heartburn during pregnancy, offer quali-

tative and statistical relief as good as that obtained with cholinergic substances.

### GASTRIC PHYSIOLOGY DURING PREGNANCY

Williams<sup>4</sup> has reviewed the changes in the stomach and its physiology during pregnancy. The normal vertical position of the stomach is altered as the gestation progresses, so that near term the fundus is found under the left leaf of the diaphragm. The greater curvature is forced nearer the cardiac sphincter by a 45° dextrorotation of the axis of the stomach. As the gastric motility decreases and the emptying time increases<sup>8</sup> the tendency to regurgitation by means of reverse waves of peristalsis increases. The increase in atony of the stomach concomitant with advancing gestation involves the cardiac end of both the esophagus and the stomach, resulting in a reflux of gastric contents into the lower esophagus. Gastric acidity decreases with advancing gestation up to the last month before delivery, when it begins to rise again.<sup>9</sup> This fact appears incompatible with the relief afforded from the alkali therapy reported so widely.<sup>10-14</sup> On the basis of the decreased gastric acidity in late gestation hydrochloric acid has been used for heartburn,<sup>10, 15</sup> with relief reported in 76 per cent of 45 patients treated.<sup>12</sup> Experimental distention of the lower esophagus, irrespective of the type of fluid or mechanical agent used, has been demon-

\*Junior assistant surgeon, Department of Gynecology, Boston Dispensary, consultant in gynecology, Joseph H. Pratt Diagnostic Hospital.

†The anion exchange resin used was marketed as resinate (700 mesh) by the National Drug Company, Philadelphia, Pennsylvania. Chemically it is a polyethylene-polyamino methylene substituted resin of diphenylol dimethyl methane and formaldehyde in basic form.

strated to cause all the symptoms of heartburn<sup>4, 16-19</sup> On this basis the modern "neuromuscular theory" of heartburn has been postulated. After secondary intermittent spasm of the cardiac sphincter the normal esophageal wave of peristalsis distends the lower esophagus with its sensitive neural endings. Heartburn results and can be completely relieved by a cholinergic drug in 81 per cent of a total of 43 patients reported<sup>2-4</sup>.

The reported failure to relieve the heartburn in 19 per cent of these pregnant patients may be due in part to the presence of unsuspected diaphrag-

matic hernia, which Rigler and Eneboe<sup>20</sup> have demonstrated in 181 per cent of primiparas during the third trimester of pregnancy. They report the incidence of hiatus hernia in pregnancy as 12.8 per cent. This has been corroborated by Evans and Bouslog,<sup>21</sup> Dwyer<sup>22</sup> and Schnepf.<sup>23</sup>

It is of course true that the majority of patients with heartburn have obtained symptomatic relief by using alkalis such as sodium bicarbonate, aluminum hydroxide and block magnesia<sup>10, 11, 14</sup>. The widespread recourse to alkalis attests to the efficacy of this symptomatic treatment, but reports limit relief obtained by alkalis to 50 per cent of these cases of heartburn<sup>12, 13</sup>. Roth<sup>3</sup> believes that the "effect of these alkalis must be largely psychic," and it must be agreed that in view of the hypo-secretion of acid that is present late in pregnancy and the equivocal results reported, this may be true.

## EXPERIMENTAL STUDY

Anion exchange resins were suggested in the management of heartburn in pregnancy for several reasons. They are biologically practically inactive, have no effect on the acid-base balance of the blood, do not cause constipation or diarrhea, have practically no significant toxicity<sup>24</sup> and serve to absorb and neutralize acids<sup>25</sup>. In addition, there is an absence of phosphate ion removal, lack of acid rebound, no chloride removal and effective pepsin inactivation<sup>26</sup>. They were found valuable in the relief of pain associated with peptic ulcer even though the progress of the ulcer was reported to be uncertain<sup>27</sup>.

A total of 35 private obstetric patients with sufficient heartburn of pregnancy to require medication were offered anion exchange resins in 0.25 gm gelatin capsules for relief of symptoms. The usual dose was two capsules repeated in one hour as necessary. More than two doses were rarely required, and relief was obtained in 31 out of 35 patients who received the medication (Table 1). As a rule the patients reported the disappearance of the epigastric and precordial burning within ten minutes of the time the two capsules of resin were taken. It is remarkable that although most women required medication three or four times a week, more than 40 per cent of those who obtained relief from the medication remained free from symptoms for seven to ten days. All these patients were treated before the last month of gestation since it has been reported that 75 per cent of untreated patients experience spontaneous remission of heartburn in the last month of pregnancy.<sup>1</sup> This factor has been all too frequently ignored in the evaluation of therapy for heartburn in pregnancy.

The average age of the patients in this group was 26.7 years, and it is of interest that 5 of the primiparas were over 30 years old. Twenty-one were primigravidas, 10 secundigravidas, 3 tertigravidas and 1 a quartigravida. The onset of heartburn occurred in the second trimester in 14 and in the last trimester in 21 cases. Only patients who voluntarily reported moderate (23 cases) or severe (12 cases) heartburn were included in this study. Relief was rapid and effective, and only those who reported unequivocal and complete relief from the heartburn were recorded as such. All patients who reported something less than complete relief are recorded as failures.

A group of 16 patients who obtained relief from the heartburn with the resin were given prostigmin bromide in 15-mg tablets for subsequent attacks, and the relief was identical with that obtained with resin. The 4 who failed to report relief of heartburn after resin medication were also offered prostigmin bromide tablets, with no improvement in their complaints.

## DISCUSSION

The relief of heartburn during pregnancy can be accomplished with variable but almost equal success by both unphysiologic empiric medication and definitive therapy based upon the modern theory of etiology. The administration of anion exchange resins orally for the relief of annoying heartburn in pregnancy has resulted in rapid relief of this symptom in 88 per cent of treated cases. This salutary result is at least comparable to that reported with prostigmin. Cholinergic drugs have been used to excellent advantage in heartburn of pregnancy in accordance with the neuromuscular-dysfunction theory now accepted by most physiologists. Yet this therapy appears to be no more effective qualitatively or statistically than anion exchange resins. This consideration suggests that there is still much to be explained in the etiologic picture of heartburn during pregnancy. The reports of relief obtained from the administration of yeast, thiamine chloride and nicotinic acid<sup>28</sup> and miscellaneous medication<sup>1, 15, 19, 29, 30</sup> merely add to the confusion. Between 8 and 20 per cent of the failures to obtain relief with any medication may be attributed to the presence of an occult diaphragmatic hernia that is reduced spontaneously post partum.

The fact that 88 per cent of the patients treated for heartburn with resin obtained complete relief makes it very unlikely that the mechanism was psychogenic. Rather, Bartlakowski<sup>31</sup> has reported that 70 per cent of esophagi studied microscopically showed islands of gastric-secreting mucosa in the distal segment. It is suggested that these gastric glands secrete sufficient acid and pepsin locally to complement that derived from the reflux of gastric juice and sufficient to discharge the sensory nerve endings of the lower esophagus, which have been primed by mechanical distention demonstrated to be present. The pepsin-inactivating role of the anion exchange resins employed in this study may play an undetermined part in the effectiveness of this medication. The resin is recommended because of its value in control of heartburn during pregnancy, its freedom from toxicity and its economy.

## SUMMARY

The etiology of heartburn in pregnancy, present in approximately two thirds of pregnant women, is believed to be a neuromuscular dysfunction of the esophagus and stomach.

Thirty-one out of 35 pregnant women with heartburn obtained complete relief from oral administration of anion exchange resins administered before the last month of gestation.

This unexpected result with an admittedly irrational, unphysiologic agent suggests that the modern theory of the etiology of heartburn has some undetermined defects.

The relief of heartburn during pregnancy can be accomplished with variable but almost equal success by both unphysiologic empiric medication and definitive therapy based upon the modern theory of etiology. The administration of anion exchange resins orally for the relief of annoying heartburn in pregnancy has resulted in rapid relief of this symptom in 88 per cent of treated cases. This salutary result is at least comparable to that reported with prostigmin. Cholinergic drugs have been used to excellent advantage in heartburn of pregnancy in accordance with the neuromuscular-dysfunction theory now accepted by most physiologists. Yet this therapy appears to be no more effective qualitatively or statistically than anion exchange resins. This consideration suggests that there is still much to be explained in the etiologic picture of heartburn during pregnancy. The reports of relief obtained from the administration of yeast, thiamine chloride and nicotinic acid<sup>18</sup> and miscellaneous medication<sup>1, 18, 19, 20, 21</sup> merely add to the confusion. Between 8 and 20 per cent of the failures to obtain relief with any medication may be attributed to the presence of an occult diaphragmatic hernia that is reduced spontaneously post partum.

The fact that 88 per cent of the patients treated for heartburn with resin obtained complete relief makes it very unlikely that the mechanism was psychogenic. Rather, Bartakowski<sup>22</sup> has reported that 70 per cent of esophagi studied microscopically showed islands of gastric-secreting mucosa in the distal segment. It is suggested that these gastric glands secrete sufficient acid and pepsin locally to complement that derived from the reflux of gastric juice and sufficient to discharge the sensory nerve endings of the lower esophagus which have been primed by mechanical distention demonstrated to be present. The pepsin-inactivating role of the anion exchange resins employed in this study may play an undetermined part in the effectiveness of this medication. The resin is recommended because of its value in control of heartburn during pregnancy, its freedom from toxicity and its economy.

## SUMMARY

The etiology of heartburn in pregnancy, present in approximately two thirds of pregnant women, is believed to be a neuromuscular dysfunction of the esophagus and stomach.

Thirty-one out of 35 pregnant women with heartburn obtained complete relief from oral administration of anion exchange resins administered before the last month of gestation.

This unexpected result with an admittedly irrational unphysiologic agent suggests that the modern theory of the etiology of heartburn has some undetermined defects.

matic hernia, which Rigler and Eneboe<sup>20</sup> have demonstrated in 181 per cent of primiparas during the third trimester of pregnancy They report the incidence of hiatus hernia in pregnancy as 128 per cent This has been corroborated by Evans and Bouslog,<sup>21</sup> Dwyer<sup>22</sup> and Schnepf<sup>23</sup>

It is of course true that the majority of patients with heartburn have obtained symptomatic relief by using alkalis such as sodium bicarbonate, aluminum hydroxide and block magnesia<sup>10, 11, 14</sup> The widespread recourse to alkalis attests to the efficacy of this symptomatic treatment, but reports limit relief obtained by alkalis to 50 per cent of these cases of heartburn<sup>12, 13</sup> Roth<sup>3</sup> believes that the "effect of these alkalis must be largely psychic," and it must be agreed that in view of the hypo-secretion of acid that is present late in pregnancy and the equivocal results reported, this may be true

## EXPERIMENTAL STUDY

Anion exchange resins were suggested in the management of heartburn in pregnancy for several reasons They are biologically practically inactive, have no effect on the acid-base balance of the blood do not cause constipation or diarrhea, have practically no significant toxicity<sup>24</sup> and serve to absorb and neutralize acids<sup>25</sup> In addition, there is an absence of phosphate ion removal, lack of acid rebound, no chloride removal and effective pepsin inactivation<sup>26</sup> They were found valuable in the relief of pain associated with peptic ulcer even though the progress of the ulcer was reported to be uncertain<sup>27</sup>

A total of 35 private obstetric patients with sufficient heartburn of pregnancy to require medication were offered anion exchange resins in 0.25-gm gelatin capsules for relief of symptoms The usual dose was two capsules repeated in one hour as necessary More than two doses were rarely required, and relief was obtained in 31 out of 35 patients who received the medication (Table 1) As a rule the patients reported the disappearance of the epigastric and precordial burning within ten minutes of the time the two capsules of resin were taken It is remarkable that although most women required medication three or four times a week, more than 40 per cent of those who obtained relief from the medication remained free from symptoms for seven to ten days All these patients were treated before the last month of gestation since it has been reported that 75 per cent of untreated patients experience spontaneous remission of heartburn in the last month of pregnancy<sup>1</sup> This factor has been all too frequently ignored in the evaluation of therapy for heartburn in pregnancy

The average age of the patients in this group was 26.7 years, and it is of interest that 5 of the primiparas were over 30 years old Twenty-one were primigravidae, 10 secundigravidae, 3 tertigravidae and 1 a quartigravida The onset of heartburn occurred in the second trimester in 14 and in the last trimester in 21 cases Only patients who voluntarily reported moderate (23 cases) or severe (12 cases) heartburn were included in this study Relief was rapid and effective, and only those who reported unequivocal and complete relief from the heartburn were recorded as such All patients who reported something less than complete relief are recorded as failures

A group of 16 patients who obtained relief from the heartburn with the resin were given prostigmin bromide in 15-mg tablets for subsequent attacks and the relief was identical with that obtained with resin The 4 who failed to report relief of heartburn after resin medication were also offered prostigmin bromide tablets, with no improvement in their complaints

it was desired to establish an aorta-pulmonary artery shunt for alleviation of the cyanotic state of tetralogy of Fallot, and when it was impossible directly to anastomose vessels of the aortic and the pulmonary systems by the Blalock or the Potts technic. One of these patients died twelve days after operation, largely from the effects of dicumarol therapy. A second died two days after operation from cardiac decompensation. The grafts in both cases were patent at post-mortem examination. In the 7 surviving patients the grafts are apparently carrying blood and have been in place from one to five months. Evidence that these grafts are patent can be adduced from the fact that all the children have continuous murmurs, which previously did not exist, and that the cyanotic states have been markedly improved.

In 3 additional patients, segments of preserved human aorta have been used as grafts during surgical correction of coarctation of the thoracic aorta. Although it is usually possible to excise a narrowed segment of aorta and directly anastomose the remaining ends, removal of the constricted areas from these 3 subjects left very long gaps in the aorta,

which precluded reuniting the remaining aortic ends. In each case a graft about 5 cm in length was employed, and in each case a lumen of full size was established for the aortic pathway. All 3 patients survived operation, they have had relief of the hypertension that preoperatively existed in the upper portions of their bodies, and they have now developed a greatly increased blood flow to the legs. These grafts have been in place only two or three months.

It is too soon to give any final evaluation of the technic of blood-vessel grafting in human cases. However, the early postoperative results are very encouraging, and they certainly warrant further trial and study when no other means are available for satisfactorily bridging a gap in a large vessel of the arterial system.

#### Albumin (Fraction I)<sup>†</sup>

**Shock.** As the product whose preparation was responsible for the initiation of the entire fractionation program,<sup>9, 11, 212-217</sup> albumin remains of first importance, but its use in the treatment of shock has become secondary. Tested successfully in civilian cases<sup>218-222</sup> of shock, it proved to be a satisfactory therapeutic agent under field conditions.<sup>11, 223, 224</sup> Unless extra fluid was given, however, dehydrated patients received less benefit from the concentrated material than normally hydrated patients did.<sup>214, 215, 221</sup> Various investigators have reported plasma-volume increases due to albumin of 8 to 18 cc per gram under different conditions. These are summarized in Table 4. Albumin uniformly produces a rise in right atrial pressure and usually causes the hematocrit to decrease. Its effect on cardiac output varies. For civilian use concentrated albumin is a convenient, easily transported, immediately available, stable, safe and effective agent for the emergency treatment of shock and is useful in accident rooms and ambulances and in doctors' bags.

**Hypoproteinemia.** Considerably less agreement exists regarding the action of albumin in chronic hypoproteinemia.<sup>216</sup> Single injections of 25 gm in

## PRELIMINARY OBSERVATIONS ON THE USE OF HUMAN ARTERIAL GRAFTS IN THE TREATMENT OF CERTAIN CARDIOVASCULAR DEFECTS

ROBERT E. GROSS, M.D.,\* ELLIOTT S. HURWITT, M.D.,† ALEXANDER H. BILL, JR., M.D.,‡  
AND E. CONVERSE PEIRCE, 2ND, M.D.§

BOSTON

FOR many years surgeons have felt the need for some technical procedure that would help in bridging gaps of the arterial system when a large vessel has been destroyed by trauma or has become thrombosed because of degenerative disease or embolism, or when certain cardiovascular abnormalities require operative correction. Extensive investigations have been conducted to further the work of other experimenters and to determine the feasibility of transferring a segment of large artery from one animal to another of the same species. Full reports of these studies will be published elsewhere.<sup>1-3</sup>

In the laboratory for surgical research sections of abdominal aorta were removed from donor dogs and were subsequently used to replace sections of the abdominal aorta of recipient dogs. Sixty-three such grafts were made, employing mongrel dogs. The studies were made in three sets of observations: vessels were removed from donor animals and implanted within a few hours into recipient dogs; segments of aorta were frozen and kept for varying periods before being implanted; and arterial segments were preserved for varying periods by storage in special nutritive solutions just above freezing before being placed in recipient animals.

In the first set of studies, there were twenty-seven grafts. After removal, the aortic segments were kept moist and in a common, domestic refrigerator for periods varying from two to seventy-eight hours, and were then grafted into recipient dogs. These recipient animals were kept under observation for as long as a year. When the segments for the grafts had been kept for only a few hours, there was a very high probability of their survival in the recipient animals. When segments were kept for about six hours and then implanted, only about two thirds of the grafts survived and remained in satisfactory condition. When specimens of aorta were kept from eighteen to seventy-eight hours before being implanted into recipient animals, the vast majority of the dogs died from thrombosis in the grafts or from rupture at the suture lines.

In the second set of studies, blood vessels from the donor dogs were rapidly frozen to  $-72^{\circ}\text{C}$  and were stored at this temperature for periods varying from two to thirty-five days before being im-

planted into recipient dogs. Twelve such grafts were made. Three quarters of these dogs died within five to thirty days from hemorrhage at the suture lines. Two grafts became partially thrombosed. One animal was kept for six months, and at autopsy the graft showed moderate intimal sclerosis. These results led to the firm conviction that storage of vessels by freezing would not be a satisfactory method for preserving arterial grafts.

In the third set of studies, aortic segments were taken from donor dogs and stored in flasks, the vessel being just covered with an electrolyte solution, to which had been added glucose (1 per cent) and dog serum (10 per cent) and a buffer, as well as penicillin and streptomycin (giving a concentration of 50 units of each per cubic centimeter), and finally a phenol-red indicator so that changes in the reaction of the solution could be determined by inspection of the fluid in the flasks. Each flask with its solution containing a segment of vessel was stored in an icebox, the temperature of which did not range beyond 1 to  $4^{\circ}\text{C}$ . Tissue-culture studies on segments of vessels preserved in this way showed that vessels were viable for as long as thirty-five to forty days in most cases. Segments of vessel that had been stored in this manner for periods of from two to ninety-eight days were implanted into recipient dogs. Twenty-four such grafts were made and the recipient animals kept from four days to ten months. There were no deaths from dehiscence or thrombosis of any of the grafts. Three animals had minor thrombi at the lines of anastomosis. The grafts were known to be carrying blood for periods as long as ten months. These vessels were studied in the living dogs by aortagrams, and were carefully studied at autopsy after death or sacrifice of the animals. The experiments indicated that arteries can be stored satisfactorily by this method in the cold for slightly more than a month and can still be used for purposes of grafting.

With the above summarized information from the experimental laboratory, it was believed that the last described method of arterial preservation might be applicable for vessel grafting in human subjects. Segments of arteries obtained within a few hours from human beings who had died in automobile accidents were collected under aseptic conditions and stored for use whenever the need for an arterial graft might arise in a human patient. Nine such grafts were used to bridge gaps between the aortic system and the pulmonary artery when

bumin diffuses into the lymph,\* remains in equilibrium with the blood, and is gradually decomposed into amino acids, which are incorporated into tissue or slowly excreted

Recently many data have accumulated that cast considerable doubt on the universal applicability of Starling's<sup>240</sup> hypothesis of edema formation and removal. Keys and his associates<sup>241</sup> produced classic starvation edema in 34 normal volunteers on a six months' European starvation diet (49 gm of protein per day). The total proteins dropped only 0.73 gm per 100 cc, and albumin-globulin ratios remained essentially unchanged with no evidence of cardiac or renal failure or thiamine deficiency. Govaerts<sup>242</sup> had independently observed the same conditions in 17 starving Belgians. Schemm<sup>243</sup> has pointed out for some time the ease of diuresis and loss of ascitic and pleural fluid in many cases on a high-fluid, low-sodium, 40-gm-protein diet when 140-gm-protein diets and plasma intravenously had failed to produce any effect. The absence of correlation between edema formation and albumin levels in nephrosis is also well known.<sup>244-246</sup> (Many have no edema with an albumin of less than 1 gm per 100 cc.) Ralli et al<sup>247</sup> and Labby and his co-workers,<sup>248, 249</sup> using intravenous liver extract, have more recently induced disappearance of ascites in chronic cirrhosis without changing the serum protein levels. It is not too surprising, then, to find albumin administration followed by diuresis with no change in serum proteins or to have albumin increase circulating proteins without mobilizing ascitic fluid.

Mankin and Lowell<sup>250</sup> sought to explain Patek's<sup>251</sup> failure to remove ascites mentioned above. In 10 patients with cirrhosis they measured the colloidal osmotic pressure of serum and ascitic fluid, ascitic fluid volume and intraperitoneal hydrostatic pressure and then varied each of these experimentally. Usually, equilibrium was quickly re-established between plasma and ascitic fluid after the transfer of a small amount of fluid between them. When the serum colloidal osmotic pressure was increased, however, there was a threefold increase in rate of transfer of albumin to the ascites, thereby preventing any osmotic removal of fluid by the blood. This seems to be further evidence that in many cases Starling's hypothesis has little to do with the persistence of cirrhotic ascites. Certainly, the rapid restoration of equilibrium makes it impossible in such cases to apply Donnan's equilibrium principle and Starling's hypothesis, which depend by definition on a "semipermeable membrane" impermeable to the protein. Inability to by-pass or circumvent the membrane is also implied. Perhaps patients with cirrhosis who have responded to albumin therapy established plasma-ascitic equilibrium more slowly or had portal pres-

sure lowered or peritoneal lymphatic drainage improved.

Blakemore<sup>251, 252</sup> reports that all 4 cirrhotic patients with ascites in whom he created a portacaval shunt for portal hypertension lost their ascites postoperatively, and 3 of these had a persistent postoperative *drop* in total protein and albumin levels. It is interesting that of the 93 cirrhotic patients in 5916 autopsies recently reviewed by Hoffman and Lisa<sup>253</sup> 87 per cent had objective ascites, and 90 per cent of these (78 per cent of the group) had evidence of portal hypertension and obstruction. Perhaps this is more important in cirrhotic ascitic formation than colloidal osmotic pressure changes are.

In nephrosis, fluid imbalance may be due to an entirely different mechanism. Luetscher<sup>254</sup> postulates an excessive tubular resorption of sodium as the basic difficulty possibly owing to a diminished glomerular filtration rate.<sup>†</sup> The injection of albumin raises the circulating protein concentration (even though ever so slightly) that draws water into the blood, increasing glomerular filtration rate and thereby diminishing the proportion of sodium resorbed and perhaps moving out some edema.<sup>‡</sup> Armstrong<sup>255</sup> tends to favor this explanation, calling it "isosmotic" addition of albumin (sustained increase in plasma volume without increase in edema-fluid osmotic pressure) as opposed to "isometric" (increased edema-fluid osmotic pressure without increased plasma volume), which fails to mobilize edema. Increased capillary permeability or restricted cardiac output may be responsible for the latter condition.<sup>246</sup>

If, on the other hand, one inclines to the theories<sup>259-261</sup> that protein normally passes the glomerulus and that proteinuria is a failure of the tubules to resorb protein rather than of the glomeruli to retain it, one must consider the possibility that the increased filtration and reabsorption of protein following an increase in serum protein might interfere with the simultaneous reabsorption of sodium. Smetana's<sup>262</sup> demonstration of dye-tagged protein resorption by normal mouse and rat tubules and Gunton and Burton's<sup>263</sup> measurement of normal proteinuria as 2 to 4 mg per 100 cc call for serious consideration of this theory.

Obviously much more work is necessary to improve understanding of the role albumin plays in edema and diuresis. Many studies are underway, and the known unpublished data far exceed the published information. Rumor brings no word of a solution, however.

**Binding.** In seeking an agent to improve the heat stability of albumin Luck and his asso-

\*Li and Reinhardt<sup>256</sup> report that the albumin content of normal rat thoracic-duct lymph is consistently much higher than that of rat cervical duct lymph or plasma.

†Schweppe and Freeman<sup>257</sup> find that the glomerular filtration rate is routinely depressed in hypoproteinemic plasmapheresed dogs. They did not report sodium studies. On the other hand, Emerson et al<sup>258</sup> find that the inulin glomerular filtration rate increased in some nephrotic cases.

‡All studies of renal function must be reviewed in relation to Cargill's<sup>259</sup> preliminary observation that renal blood flow measurements following albumin administration are one third higher when measured by renal vein catheterization than when done by indirect techniques.

pressure (10 to 20 per cent), a smaller increase in total circulating albumin than the amount injected, a slight rise in circulating globulin, an increase in proteinuria (chiefly albumin and alpha<sub>1</sub> globulin) and a slight rise in urine volume without change in chloride excretion or albumin or globulin clearance. Within 48 hours most effects have disappeared, and the albumin has left the circulating plasma without being quantitatively excreted in the urine. Doses of 50 gm given daily for two to thirty days to patients with chronic Bright's disease are reported by Thorn et al<sup>227</sup> to produce moderate diuresis best in patients with edema, low proteins, no nitrogen retention and normal blood pressure. This stops when albumin is withdrawn. Others<sup>228</sup> have observed, however, that after sixty to ninety days' treatment diuresis may continue to dryness. Perhaps a spontaneous diuresis was initiated. DeSanctis and Sullivan<sup>229</sup> have also reported a successful remission (six months) and rise in serum protein to normal in a four-and-a-half-year-old boy with nephrosis receiving 15 gm of albumin daily for sixty days, in addition to a low-sodium, high-protein diet. Similar responses were seen in 4 more nephrotic children still under treatment, 2 of whom lost their ascites on this regimen.

In cirrhosis equally confusing results have been observed. Five patients on low-salt, low-fat, high-protein, high-vitamin and high-liver diets were given 50 gm of albumin daily for one to ten days by Thorn et al<sup>230</sup>. An immediate diuresis was not maintained, and no remarkable effects on ascites were noted. Patek and his associates<sup>231</sup> report a similar failure in 3 patients with chronic cirrhosis treated thirteen to sixteen days. Apparently, the rate of transfer of albumin from plasma to ascitic fluid increased threefold during treatment.

The largest series of cases of albumin-treated cirrhosis followed the longest time was recently published by Kunkel et al<sup>232</sup>. Using doses of 4 to 80 units (100 to 2000 gm) of concentrated albumin, they treated 17 patients (5 with ascites of short duration, 4 with long-standing ascites, 6 with severe liver damage following infectious hepatitis or biliary cirrhosis and 2 with low serum albumin but no ascites or edema), 14 of the 15 patients with ascites lost their fluid after albumin. High-vitamin, high-protein, high-calorie diets were given without salt restriction. No difference in action of high salt and salt-poor albumin was seen. Patients with marked portal obstruction, high antidiuretic titers in the urine or long-standing ascites proved most resistant. Those with low serum albumin levels and ascites of short duration (especially after infectious hepatitis) responded most readily. Many patients volunteered the information that they developed a feeling of well-being and increased appetite after albumin. Careful caloric and nitrogen balance studies confirmed the truth of this subjective observation. These results help to explain

the failures reported by Thorn and his co-workers<sup>230</sup> and Patek et al,<sup>231</sup> who used smaller doses for shorter periods, and in the Patek series the most difficult group (ascites of nine to twenty-four months' duration) were being treated. The observations of Armstrong<sup>233</sup> and Gibson,<sup>234</sup> using doses of 500 to 700 gm of albumin, more nearly parallel those of the Kunkel group<sup>232</sup>.

Obviously, chronic hypoproteinemias are very difficult to affect. The edema of a terminal case of lupus erythematosus failed to respond to 400 gm of albumin<sup>234</sup>. Acute conditions, however, seem to be more sensitive. Jacoby et al<sup>235</sup> report the excellent response of 2 infants with erythroblastosis fetalis and edema to 30.0 and 12.5 gm of albumin, respectively, which produced complete relief of symptoms and permitted survival.

**Metabolism.** Studying the fate of albumin, Eckhardt and his associates<sup>236</sup> maintained 5 normal subjects on albumin by mouth or vein as the sole source of nitrogen for seven to sixteen days. They observed that 37.5 gm of albumin was sufficient to maintain a positive nitrogen balance when given by vein, but 50 gm was required by mouth. After the albumin had been discontinued, the excess disappeared from the circulation on a four-day to six-day 50 per cent disappearance curve, reaching normal levels in three weeks. The addition of tryptophane and isoleucine (two major essential amino acid deficiencies of albumin<sup>237</sup>) did not affect these observations.

Thorn et al<sup>230</sup> achieved no therapeutic effect when they fed albumin to a patient with cirrhosis. They did observe, however, that the onset of urea nitrogen excretion was delayed several days longer after albumin was administered by vein than when given by mouth. This led Albright and his co-workers<sup>238</sup> to study the metabolism of albumin. Giving an osteoporotic female patient 50 gm of albumin intravenously daily for twelve days, they obtained the following "nitrogen balance sheet" twenty-four days after the last injection: nitrogen injected 82.94 gm, burned 66.51 gm, converted to protoplasm 8.29 gm and unchanged 8.14 gm. These figures indicate considerably less conversion to protoplasm, slower burning and more protein storage than was found in 3 patients similarly studied after receiving whole plasma. Whether this is a peculiarity of albumin metabolism or a vagary of this particular patient with disturbed calcium and phosphorus metabolism was not determined.

**Mechanism of action.** The behavior of injected albumin presents two challenging questions. Where does it go from the blood stream? How is diuresis accomplished in certain cases without a sufficient rise in circulating protein to alter the colloidal osmotic pressure significantly?

Eckhardt et al,<sup>236</sup> after observing the metabolic experiments just described, hypothesized that al-

report 100 successful infusions of this material (average dose of 400 cc), with only 3 per cent reactions — chills and fever and no anaphylaxis on reinfusion ten to fifteen days later. Melka et al.<sup>291</sup> were unable to sensitize animals with it, and found that the treatment had not diminished its osmotic pressure. Hughes, however, was unable by this method or by that of Lewis<sup>292</sup> to lower the reactivity of the recrystallized albumin used by Wangenstein et al.<sup>287</sup>

Gelatin (bovine, fish or modified) has been extensively investigated and reported.<sup>11, 14, 293</sup> It is safe, nonantigenic, effective in the immediate treatment of shock,<sup>294</sup> capable of producing a positive nitrogen balance and not usually deposited in tissue cells.<sup>295, 296</sup> It is rather quickly excreted, however, tends to depress the serum albumin level and has not been extensively investigated in the treatment of chronic hypoproteinemia.

Human hemoglobin and globin were discussed above. There are no reports of attempts to prepare bovine globin for intravenous use.

Both acacia<sup>297, 298</sup> and pectin<sup>299</sup> have been shown to be deposited in liver cells, possibly leading to damage and impaired function. Both leave the blood stream rather quickly.

The following synthetic preparations are also ineffective: glutamic acid polypeptide, sodium glycerol polysuccinate, dextran<sup>300</sup> — a Swedish glucose polysaccharide from beet sugar, with a molecular weight of 100,000, that is safe but completely excreted in twenty-four hours, and a Russian "colloidal infusion of non-anaphylactogenic protein from milk casein"<sup>301</sup> with deficiencies similar to those of dextran. The Russian "plazmol S-25"<sup>302</sup> is apparently a "tissue-therapy" product of human plasma similar to antireticular cytotoxic serum and not a blood substitute.

Amino acids and protein hydrolysates are composed of molecules small enough to diffuse through normal semipermeable membranes and perform little osmotic function. Their metabolic aspects are discussed below.

Human ascitic fluid is used from time to time but is usually too low in protein to be effective. Philippine investigators<sup>303</sup> report success in treating a nephrotic patient with 100 cc of material heated at 60°C for two hours. This has not been repeated.

A minimal molecular diameter of 30 angstrom units seems necessary for retention in normal blood vessels. Few proposed substitutes approach this size (Table 3). Until such a compound is discovered, albumin, plasma and blood remain the most reliable therapeutic agents now available.

#### PROTEIN THERAPY

##### Metabolism

With the increasing number of amino acid and proteinoid preparations available for clinical use,

it is important to review certain aspects of protein and amino acid metabolism as a basis for rational clinical therapy.

The usefulness of a protein or amino acid mixture is apparently related to its composition, route of administration and simultaneous carbohydrate intake. Rose<sup>304</sup> demonstrated the "essential" nature of 10 amino acids in the rat (8 in human adults)\* "those which cannot be synthesized by the animal organism, out of the materials ordinarily available, at a speed commensurate with the demands for normal growth." Not until later, however, was it appreciated that for optimal utilization the missing essential acids must be supplied reasonably near the same time that the incomplete protein is ingested or else much of the incomplete protein will not be utilized. A delay of two<sup>305</sup> to six<sup>306</sup> hours between "incomplete" and "essential" acid intake is sufficient to prevent utilization of the former. This may explain why some proteins such as soy bean with satisfactory total amino acid analyses have low nutritive value (some of the essential amino acid components may be more difficult to digest and more slowly absorbed).

Many investigators are beginning to believe that maximal protein utilization depends on factors other than essential amino acids. The "doubly depleted" dogs (anemic and hypoproteinemic) of Whipple et al.<sup>307, 308</sup> could manufacture hemoglobin and plasma protein satisfactorily on the ten crystalline essential amino acids but failed to maintain weight. Womack and Rose<sup>309</sup> and Woolley<sup>310</sup> noted the same difference in mice fed crystalline amino acids as opposed to casein hydrolysates. They believed, however, that both sets grew — only that the hydrolysate group grew maximally. Woolley attributes this property to a peptide or peptide-like substance, streptogenin, separated from highly purified protein by tryptic digestion but destroyed by hydrolysis. Christensen<sup>311</sup> has observed that casein peptides are less readily utilized than free amino acids and suffer considerable loss when given intravenously. Perhaps this explains the observation frequently reported that protein hydrolysates and amino acid mixtures are better utilized when given orally than intravenously.<sup>312-314</sup>

Cannon et al.<sup>305, 315, 316</sup> believe that a critical level of simultaneous carbohydrate intake is required to maintain a positive nitrogen balance on any amino acid intake. Exceeding that, however, the addition of extra calories has no apparent effect, merely adding adipose tissue. They estimate the critical value as 1240 calories for rats or 1500 calories for man per square meter of body surface per day. Kozoll and his co-workers<sup>313</sup> found 1000 calories per day adequate in man.

The question of protein storage has been much discussed.<sup>317</sup> Originally postulated as separate en-

\*Leucine, isoleucine, valine, lysine, threonine, tryptophane, phenylalanine and methionine for man; and arginine and histidine for the rat.

ciates<sup>264-267</sup> showed that considerable protection was derived from the binding to albumin of fatty acids and related compounds, which were anions with a nonpolar group. The effectiveness of this protection increased with chain length up to 12 carbons. This ability to bind other substances was found to be a property of albumin almost exclusively, probably related to its molecular conformation. Although Bennhold<sup>268</sup> had suggested in 1932 that such a mechanism might exist for transportation of substances in the blood, this was the first work to investigate it thoroughly. There are many examples of the usefulness of this property.<sup>269</sup> It may be part of the antibody defense system, coating bacteria to permit phagocytic ingestion (as pointed out under "sludged blood" above). Certainly, it is necessary for the blocking of anticomplementary action of gamma globulin to permit normal complement-fixation reactions. It may also serve to make lipid hormones water soluble, protect against hemolytic action of fatty acids and possibly salvage valuable blood constituents of small molecular size by preventing the necessity of their filtration and reabsorption. Even osmotic-pressure calculations are affected, since one molecule of albumin can bind six chloride ions.<sup>270</sup>

Davis and Dubos<sup>271-277</sup> have described in a number of communications a very practical application of this property. Seeking to dissolve the waxy layer of the tubercle bacillus with Tween 80 (polyoxyethylene sorbitan monooleate) Dubos found that it stimulated and at other times inhibited submerged culture growth. Relating the inhibition to unesterified oleic acid content, it was found by chance that serum albumin bound the oleic acid and the Tween, and then stimulated growth so that inoculums of 2 or 3 bacteria could be successfully cultured. It is not a growth factor—merely a protecting mechanism enabling growth to become established.

The most recent example of the importance of albumin binding is reported by Tompsett et al.<sup>278</sup> in investigating the clinical failure of penicillin K. Studying X, G, dihydro F, and K, they found that albumin bound them all in varying degrees from 47 per cent for X to 91 per cent for K, checking quite well with the 85 to 90 per cent loss of activity of K in studies in vivo compared with studies in vitro. It is important that all in vitro antibiotic studies include albumin in the medium used.

**Miscellaneous** The use of human or bovine albumin in 25 or 30 per cent solution<sup>280</sup> or mixed with plasma I<sup>4379</sup> has markedly improved the specificity and accuracy of Rh typing and Rh blocking antibody tests, facilitating the prenatal management of mothers of potentially erythroblastotic children. In like manner Neber and Dameshek<sup>280</sup> used albumin as a diluent in antibody tests of hemolytic syndromes and were able

to demonstrate circulating warm antibodies not found by routine methods in 5 of 17 patients.

Another useful new technic involving albumin is reported by Ferrebee et al.<sup>281</sup> and Vallee and his associates<sup>282</sup> for the separation of leukocytes from whole blood by flotation. When two parts of albumin solution of specific gravity 1.079 are added to three parts of heparinized blood and centrifuged, the plasma and leukocytes form a layer above, and the erythrocytes a layer below the albumin. The leukocytes are easily pipetted off and may be separated from the plasma by saline dilution and further centrifugation.

### BLOOD SUBSTITUTES

The expense and difficulty involved in large scale procurement of human blood and its derivatives have stimulated the search for satisfactory substitutes of animal, vegetable or synthetic origin. Janeway and Oncley<sup>14</sup> have summarized the physicochemical and clinical background of this search.

Bovine albumin is chemically most like human albumin, and much effort has been expended to develop it as a satisfactory substitute.<sup>283, 284, 285-287</sup> Unfortunately, a certain amount of antigenicity remains, even in preparations carefully recrystallized many times. Large-scale investigation was terminated in 1942 upon the death of 1 of 60 volunteers receiving 25 gm. each.<sup>288</sup> Myocardial necrosis was found post mortem. Twenty-four of the volunteers developed symptoms ten to thirty-three days after injection, with fever, purpura and hepatic, renal and cardiac damage (as demonstrated by electrocardiographic changes) of varying degree and duration. Many of these never showed demonstrable circulating antibodies to bovine albumin, and some recovered while bovine albumin was still detectable in the blood.

Wangenstein and his co-workers<sup>287</sup> did not encounter this type of reaction and have continued investigation. They recently reported 469 injections to 410 patients with 2.9 per cent immediate and 9.2 per cent delayed reaction—none fatal. Immediate reactions were anaphylactoid or pyrogenic. Delayed reactions occurred in twelve to twenty-four days as urticaria, erythema, myalgia, arthralgia and fever. The severest cases received most relief from intravenous procaine (1 gm. in 250 cc. of saline solution injected over a period of an hour). Seven autopsies of patients dying from other causes showed no disease attributable to bovine albumin. Despite this and despite its effectiveness in shock, they recommend that it not be used until further despeciated. Attempts to relate antigenicity to sulfhydryl and disulfide groups have not been confirmed.<sup>288</sup>

Edwards<sup>289</sup> attempted despeciation of whole bovine plasma by heating to 72°C. for thirty minutes and adding 0.2 per cent formalin and 0.34 per cent ammonia. Cordier and Demirleau<sup>290</sup>

the development of purple "spectral" bands permitting identification. A rough quantitative separation can be achieved by the use of a large paper turned 90° after the first "progression" is complete, and placed with the next edge in a different solvent (collidine). This effects further separation at right angles and provides areas for quantitative comparison, especially when "standard mixture" solutions are run simultaneously.

### Total Protein

The *copper sulfate* method of Phillips et al.<sup>348</sup> has come to be the simplest and most widely used of the specific-gravity methods for protein determination. It is reasonably accurate<sup>349-352</sup> for routine survey work, the largest error occurring with fatty, lipid-rich plasmas.

A *unimolecular film* method has been recently adapted by Gunton and Burton<sup>263</sup> from Bateman,<sup>353</sup> Gorter and Grendel<sup>354</sup> for use as a simple, economical, rapid clinical micromethod for determining protein in normal urine and spinal fluid. The test fluid is dropped on the surface of a 3 per cent salt solution to form a unimolecular film, and the area occupied by it is measured at standard film pressure. This is done by the addition of a drop of indicator oil and "sweeping" of the surface with a barrier until the oil is compressed sufficiently to produce a standard interference color indicating a standard pressure. Area is proportional to protein concentration within limits. It is accurate to 2 to 3 mg of protein per 100 cc. The proteins in the urine of 100 normal subjects averaged 3.7 mg per 100 cc by this method.

### Protein Fractions

The development of a clinically adaptable *electrophoretic* method by Tiselius<sup>355</sup> opened the way to a more accurate differentiation between the various plasma proteins. The clinical information obtained in this way has been summarized by Stern and Reiner<sup>356</sup> and Luetscher.<sup>18</sup> Stimulated by discrepancies between electrophoretic results and those of classic chemical fractionation,<sup>357-366</sup> several groups have run comparative series. Petermann et al.<sup>361</sup> checked 31 patients by electrophoresis and Howe<sup>367</sup> (22.2 per cent sodium sulfate) fractionation. Albumin by the latter method was 7 to 36 per cent higher, closely approximating the sum of electrophoretic albumin and alpha-globulin, which frequently showed reciprocal changes on serial study. Chow<sup>368</sup> obtained similar results on 198 samples. Protein hydrolysate therapy frequently caused variations in "Howe albumin" not reflected by electrophoresis. Although subject to inaccuracies itself<sup>369</sup> and separating together some globulins (especially beta) that have nothing in common but their mobilities, electrophoresis remains the most reliable yardstick for protein determinations at present available.

The *immunochemical precipitin* method of Heidelberger and Kendall<sup>370</sup> and Goettsch<sup>371</sup> uses rabbit serums sensitized against specific protein fractions, and measures these fractions in blood or spinal fluid by antigen-antibody precipitation and determines the degree of reaction by measuring the nitrogen content of the precipitin produced.<sup>372</sup> It is extremely accurate, and has been completely described in a new book by Kabat and Mayer.<sup>373</sup> Chow<sup>374</sup> has modified it to permit turbidimetric measurements of amount of precipitin.

*New methods* Several new technics have been proposed to give a chemical fractionation method for clinical use approximating electrophoretic separation. Pillemer and Hutchinson<sup>359</sup> used methanol to precipitate everything except albumin. This checks within less than 8 per cent of electrophoresis but requires a cold room or cold centrifuge. Milne<sup>375</sup> employed 26.8 per cent sodium sulfate to precipitate globulin and agreed with electrophoresis within 8 per cent, which was closer than Majoor's<sup>376</sup> results using the same method. Popjak and McCarthy's<sup>377</sup> saturated magnesium sulfate method gave approximately the same agreement, or better according to Schwartz.<sup>366</sup> C. Cohn et al.<sup>365</sup> use a 28 per cent sodium sulfite precipitant and colorimetric method<sup>378</sup> to obtain albumin values within 2 per cent agreement with electrophoresis in a small series. Albanese and his associates<sup>379</sup> propose a microcolorimetric method for determining both albumin and globulin involving a Sukaguchi reaction and arginine determination following 22 per cent sodium sulfate precipitation. Unfortunately, they have not reported a parallel series of electrophoretic determinations. Jager et al.<sup>380, 381</sup> have tried 33 per cent ammonium sulfate to precipitate only gamma globulin, which they have followed as a clinical indicator in rheumatic disease.

There remains an urgent need for a new fractionation method adaptable to routine clinical laboratory use so that change in the plasma proteins can be more accurately followed.

### SUMMARY

It is hardly possible to summarize a review. Some points, however, deserve re-emphasis.

Blood drawn into cooled bottles containing acid-citrate-dextrose solution (ACD) and maintained at 4-10° C will, when transfused after twenty-one days' storage, show 80 per cent cell survival for at least five days after transfusion.

By the use of the substitution technic, 350 cc of Rh— blood can replace 75 per cent of an erythroblastotic infant's blood.

Recipients other than Group O should not be given O blood unless its antiagglutinin titers are less than 1:64 or Witelsky's A and B substances have been added.

ogenous and exogenous "deposits," the concept was changed to one of "dynamic equilibrium," following Schoenheimer's<sup>318</sup> demonstrations with isotopes that body proteins (including tissue and antibody components) are constantly being interchanged. The body protein reserves (some twenty-five to thirty times as great as plasma protein<sup>319</sup>) are capable of great depletion,<sup>317, 320, 321</sup> at times greater than plasma protein levels indicate. This was nicely demonstrated by Localio et al.,<sup>322</sup> who analyzed the protein content of fascia, peritoneum and muscle in 17 controls, 21 debilitated patients and 17 patients with wound disruption. The fascia figures seemed most reliable and averaged 29.00 gm. per 100 cc for controls and 18.73 gm per 100 cc for the wound disruptions. Of the latter group, 11 had total serum proteins over 6.1 gm and 2 of these even had albumins above 3.7 gm per 100 cc. Part of the rapid depletion of reserve protein in starvation may be due to the body's effort to obtain certain poorly stored essential amino acids. If they are present in low concentration, the remaining components may be wasted in large quantity to provide an adequate supply of the needed constituent.<sup>323</sup> When an adequate intake of all the essential amino acids was given in addition to a high-protein, high-calorie diet, Emerson and Binkley<sup>324</sup> were able to show in 3 patients that nitrogen utilization was increased two or three times as much as the total nitrogen intake, whereas raising the dietary protein intake could not increase nitrogen utilization any more than the nitrogen intake increased. Apparently the presence of the essential amino acids permitted a more efficient utilization of dietary and body nitrogen.

### Use

Kremen,<sup>16</sup> Elman<sup>16, 321</sup> and Ravdin<sup>17</sup> have written excellent reviews on this subject. Blood, plasma, and amino acids can all be used to maintain nitrogen balance. Preoperative protein therapy is especially desirable in surgical patients showing any anemia or hypoproteinemia, since blood proteins rate the highest priority in the "ebb and flow" of protein between organs and blood,<sup>325</sup> and are maintained at the expense of the tissues, thus retarding healing<sup>322, 326</sup> even in patients with apparently high hemoglobin and plasma protein values.<sup>327</sup> Extremely large amounts may be required ordinarily,<sup>328, 329</sup> and in gastric cancer after operation several observers feel that there is a defect in the mechanism for protein synthesis that demands an even greater amount of protein therapy.<sup>330-332</sup>

Considerable interest has been aroused by the treatment of intractable pain in peptic ulcer with casein hydrolysate used by Co Tui et al.<sup>333</sup> In doses up to 0.6 gm of nitrogen per kilogram of body weight, as well as carbohydrate (12.5 gm per kilogram daily), they obtained immediate re-

lief in 48 of 164 cases and eventual relief in all but 16 who followed the diet and 18 who could not tolerate it. It is most important that large and frequent doses be given if any acid neutralization is to be obtained.<sup>334</sup>

### Reactions

Reactions to blood and plasma were discussed above. Amino acid and protein hydrolysate reactions are chiefly nausea, anorexia, vomiting, thrombophlebitis at the site of the injection and occasionally pyrogenic chills and fever. Apparently, nausea, anorexia and vomiting are more related to composition of the mixture than to speed of infusion or blood level of alpha amino nitrogen or dicarboxylic acids.<sup>335, 336</sup> The only remedy proposed for the thrombophlebitis has been to select one vein for administration, start peripherally and progress up the arm as it closes off.<sup>332, 337</sup> The crystalline amino acid mixtures and a lyophilized casein hydrolysate seemed to be the two preparations freest from reactions of those reported.<sup>333, 334, 336, 338</sup>

## LABORATORY METHODS

### Amino Acids

The increasing need for accurate information on amino acids has led to the development of two important analytical methods.

The *microbiologic assay* developed by Snell<sup>339-341</sup> from earlier work by Schopfer<sup>342</sup> is now the most accurate and reliable method available for assaying most amino acids<sup>343</sup> and many vitamins. By the use of the growth requirements of certain bacteria, especially lactobacillus, a culture medium is prepared containing all necessary ingredients except one amino acid, which is to be investigated. This is added in different concentrations to the medium and inoculum in a series of culture tubes and incubated, and the amount of growth obtained is measured by titration of the lactic acid produced. Growth is plotted against concentration to give a standard curve. The procedure can then be repeated with an unknown replacing the standard amino acid, and its concentration can be obtained from comparison with the curve. This method is quite accurate and is now widely used in large laboratories.

A less complicated qualitative method of *paper chromatography* was recently described by Gordon et al.,<sup>344</sup> Consden and his associates<sup>345</sup> and Dent.<sup>346, 347</sup> A small drop of test fluid is spread along a line near the end of a long strip of filter paper (2 by 45 cm). This end is then placed in a container of phenol and left to hang in a moist chamber until the phenol has progressed down the paper 25 cm past the test solution. The paper is dried, sprayed with ninhydrin and dried again. The various amino acids have different solubilities and are carried with the solvent different distances, as shown by

The normal erythrocyte life span is probably one hundred and ten to one hundred and thirty days.

All unhealthy people show a tendency for their erythrocytes to stick together and capillaries to constrict, resulting in diminished oxygen supply to various tissues. This is known as blood sludge.

The American Red Cross is supporting a national peace-time blood-procurement program to provide free blood and its derivatives to everyone.

A presumably noninfected person who has received malaria-suppressive therapy should wait at least two years without symptoms before donating blood. No person who has had malaria should ever donate blood to be used whole.

Because of the danger of homologous serum hepatitis, pooled plasma should be used only when nothing else is available. Transmission by whole blood is much less frequent. No satisfactory specific prophylaxis or treatment has been developed. The routine heating of salt-poor albumin at 60°C for ten hours destroys the hepatitis etiologic agent.

Fibrin foam and film are finding increasing use in all branches of surgery for hemostasis and tissue-defect repair. Recent film uses include eardrum repair and blood-vessel anastomosis.

Antihemophilic globulin found in Fraction I is an effective temporary treatment for hemophilic bleeding.

Gamma globulin is an effective prophylactic agent against measles and epidemic hepatitis.

Serum iron is carried in the plasma in combination with a beta globulin, which is usually only about 34 per cent saturated. The normal iron-binding capacity is 314 microgm per 100 cc, and the iron content 106 microgm per 100 cc.

Some cases of nephrosis and some of cirrhosis have responded to large amounts of albumin (700 to 2000 gm), but others have not.

Data from the use of large amounts of albumin contribute further evidence that in many cases of hypoproteinemia the Starling hypothesis is inapplicable or of minor importance.

Albumin has a peculiar property of binding to itself many nonpolar anion compounds. This has facilitated the development of an excellent culture medium for tubercle bacilli, since the albumin binds growth-inhibiting oleic acids. It also explains the ineffectiveness of penicillin K in vivo, since the penicillin is 91 per cent bound by albumin. This may also be responsible for the useful role albumin plays as a diluent in many immunologic reactions.

Leukocytes can be almost quantitatively separated from erythrocytes by the use of an albumin solution of proper specific gravity.

No satisfactory substitute for blood has yet been developed. Bovine albumin is most effective but has a 10 per cent reaction rate. Gelatin is non-reactive but is rather quickly excreted.

For optimal utilization, amino acid mixtures should be given by mouth, should contain all essential amino acids and should be accompanied by a minimal carbohydrate intake of 1000 to 2500 calories per day.

Amino acid reactions seem to be related more to composition than speed of administration—crystal line mixtures give least difficulty.

The microbiologic assay and paper chromatography are useful analytic methods for amino acids.

The classic 22.2 per cent sodium sulfate (Howe) fractionation method for determining serum albumin gives values 10 to 40 per cent too high, since it includes alpha<sub>2</sub> globulin, which may vary reciprocally with albumin. Several newer methods are presented attempting to rectify this error in routine clinical laboratory determinations.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

### Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

BENJAMIN CASTLEMAN, M.D., *Associate Editor*

EDITH E. PARRIS, *Assistant Editor*

### CASE 34421

#### PRESENTATION OF CASE

**First admission.** A fifty-one-year-old retired policeman entered the hospital with complaints of intermittent dysphagia, crampy pains in both calves, which were unrelated to exercise, tight feelings in the left chest, right shoulder and upper arm, and low back pain relieved by lying down, all of eighteen months' duration.

Except for chronic maxillary sinusitis treated ten years previously by Caldwell-Luc operations, he had always been in good health until two years before entry, when he was admitted to another hospital. The complaints at that time were exertional dyspnea and sharp pains beginning at the right costal margin, which radiated to the scapular region. Physical findings were basal rales in both lungs, moderate tenderness in the right upper quadrant, mild jaundice and moderate ankle edema. A Graham test showed a normal gall bladder. An upper gastrointestinal series was normal. An electrocardiogram showed alterations in the ST segments and T waves and absence of the R waves in all the precordial leads. The patient was hospitalized for approximately four months at that time, and toward the end of his stay he first noted difficulty in swallowing solid foods and also began to notice pain and stiffness of the left leg on arising in the morning. The leg pain and stiffness continued, and a year prior to admission he was admitted to another hospital for study. On several occasions he coughed up bloody sputum, and

bilateral superficial femoral-vein ligations were done.

Physical examination revealed a well developed and well nourished ruddy man in no acute distress. There was elevation of the left shoulder on inspiration. A few coarse rales were heard at the left base posteriorly. The heart was not enlarged to percussion. There was a Grade I apical systolic murmur. The remainder of the examination was entirely negative.

The temperature was 99°F, and the pulse regular at a rate of 80. The blood pressure was 150 systolic, 100 diastolic.

Examination of the blood showed a red-cell count of 5,380,000, with a hemoglobin of 12.5 gm, and a white-cell count of 10,300, with 75 per cent neutrophils. The sedimentation rate was 1.33 mm per minute, uncorrected, and 1 mm per minute corrected. Examination of the urine revealed a specific gravity of 1.024 with a ++ test for albumin and the sediment contained 1 to 5 white cells and rare hyaline and granular casts per high-power field. A stool specimen was guaiac negative. The fasting blood sugar was 108 mg, the nonprotein nitrogen 28 mg, and the total protein 7.1 gm per 100 cc. The spinal fluid was entirely normal. An electrocardiogram showed depression of the ST segments in Leads 2 and 3, a flat T wave in Lead 1 and upright T waves in Leads 2 and 3, absent RV<sub>1</sub>, prominent QV<sub>1</sub>, QV<sub>2</sub>, and QV<sub>3</sub>, elevated STV<sub>1</sub>, STV<sub>2</sub>, and STV<sub>3</sub>, upright TV<sub>2</sub> and TV<sub>3</sub>, inverted TV<sub>1</sub>, elevated STVL and depressed STVF.

X-ray examination of the chest showed blunting of the costophrenic sinuses and emphysematous areas in the left lower lobe. The heart was prominent in the region of the left ventricle; the aorta was somewhat tortuous. The cardiothoracic ratio was 14.5/32.5. A barium swallow showed a constriction in the midportion of the esophagus, with moderate dilatation proximal to the constriction. The constriction extended over approximately 2 cm. There was no evidence of shelf formation. Films of the dorsal and lumbar spine were not remarkable.

Esophagoscopy was done, and there was an area of narrowing 32 cm from the teeth. The margins were fairly smooth but unusually indurated. Biopsies

ness in the calves of the leg. The more I think about this, the more I am inclined to think that there is one possible diagnosis that might explain all the symptoms and signs rather than to say that he had thrombophlebitis, pulmonary infarcts, cardiospasm and chronic coronary-artery disease with ruptured myocardium. Before this diagnosis is mentioned, the possibility of carcinoma of the esophagus must be considered. However, I think that I have no more right at this post-mortem discussion to call this carcinoma than those who treated the patient had at the time he was alive. The x-ray findings at the time he was in the hospital apparently were interpreted as those of a benign stricture or cardiospasm rather than those due to any new growth in the esophagus itself. This was further borne out by the esophagoscopy, and the biopsy taken at that time recorded only inflammatory changes. That, of course, does not rule out the possibility of a malignant lesion deeper than the level from which the biopsy material was obtained. I think that I will say there was a possibility of cancer with nerve-root involvement, and such involvement posteriorly could have explained some of the chest pain and also the leg pain. However, I believe that that probably was not so.

Another diagnosis, although it is perhaps a little far-fetched because of the duration of the symptoms, is that of a dissecting aneurysm with final rupture of the aorta. I have never heard of one giving symptoms for two years before death, but I have heard of some that have gone for a year. The fact that this man had pain in the back, in the legs and in the chest before he developed dysphagia leads me to believe that he might have had an aneurysm. First of all, we know he had generalized arteriosclerosis, and I am going to say that he had an atheromatous aorta and that the presenting symptoms early in the illness were those of early dissection of the aorta. We can even explain the vomiting of blood on that basis. If there was a slow leakage into the lower trachea or bronchus from the aorta, the progressive dysphagia and the difficulty in swallowing in spite of bouginage lead me to believe that there was increasing inflammation of the esophagus. I think that if it had been due to cancer, the lesion would have been visible in some of the films. A mass, a blood vessel and an aorta slightly distended, possibly eroded might not have shown up in the x-ray film. The final symptoms, which include pain in the arm, in the flank and in the legs radiating around the costal margin, give such an unusual distribution of pain that again I cannot explain it in any way other than by a slowly dissecting lesion of the aorta.

I have considered the possibilities of simple cardiospasm with generalized arteriosclerosis, thrombophlebitis and old pulmonary infarcts. Having considered carcinoma of the esophagus and metastasis to the spine that we have not been able to

demonstrate and having considered that he may have had coronary thrombosis and that the final episode was one of ruptured heart, I think I am going to stick my neck out and make a final diagnosis of a slowly dissecting aneurysm of the aorta, which possibly had eroded into the bronchial tree at some stage of the game, causing bleeding, and that it finally ruptured producing massive, fatal hemorrhage.

A PHYSICIAN: Were the heart sounds weak or strong?

DR TRACY B. MALLORY: Dr Scannell, can you answer that?

DR J. GORDON SCANNELL: I do not remember particularly—our attention was evidently not called to them.

DR M. ISAACSON: I should like to ask Dr Ellis what he thinks of the possibility of aneurysm of the posterior wall of the left ventricle on the basis of infarct causing esophageal constriction. A few cases have been reported, and I\* recently reported a case of myocardial aneurysm causing esophageal obstruction. This case is similar.

DR ELLIS: I think it is a distinct possibility. The reasons for thinking it probably is an aortic rather than a myocardial aneurysm are the slowly progressive symptoms over a long period and the distribution of pain. He may well have had a ruptured myocardial aneurysm.

DR WYMAN: From the x-ray point of view the diagnosis of cancer is quite feasible. We have seen a good many that did not show definite shelf formation but merely narrowing with or without ulceration centrally. I wonder if the last chest film does not suggest lymphatic spread of metastases to the lung fields.

DR JACOB LERMAN: I would like to ask if a circular constriction of that sort could be explained on the basis of aneurysm, with pressure on one side, anterior or posterior. It is hard to conceive of an aneurysm producing that picture.

DR WYMAN: It would not usually unless associated with inflammatory reaction and constriction.

#### CLINICAL DIAGNOSES

Coronary occlusion  
Stricture of esophagus, unknown etiology

#### DR ELLIS'S DIAGNOSIS

Dissecting aneurysm of aorta, with rupture

#### ANATOMICAL DIAGNOSES

Coronary arteriosclerosis with thrombosis  
Myocardial infarction, left ventricle  
Acute bacterial endocarditis mitral valve  
Benign stricture of esophagus  
Lipoid pneumonia  
Arteriosclerosis, general

\*Isaacson M. Myocardial aneurysm causing esophageal obstruction: report of case presenting double cardiac aneurysm with severe dysphagia necessitating gastrostomy. *New Orleans M J* 100:565-57, 1945.

were taken and reported as acute and chronic inflammation

During the one-month stay in the hospital repeated barium swallows were done, with little change in the appearance of the lesion. The original complaints persisted, but the patient was able to eat semisolid foods and was only occasionally troubled by regurgitation. Dilatation of the esophagus was started, and the patient was discharged from the hospital.

*Final admission* (six months later) The patient was seen at approximately one-week intervals over the next five months for bouginage, but despite this was able to eat only semisolid and liquid foods. The pains in the chest, back and leg were constantly present during this period. One week before admission he was seen in the Emergency Ward with complaints of severe, sharp, stabbing pain in the left calf, left lower chest and flank, and right upper arm. At this time it was noted that the blood pressure was 105 systolic, 70 diastolic, but there were no other changes. X-ray study of the chest showed moderate enlargement of the heart in the transverse diameter. There was also moderate fibrosis in both lung fields, but no definite pulmonary edema. Electrocardiograms revealed changes from the previous one with prolongation of the QRS complex, slight elevation of the ST segment and more marked elevation of STV<sub>2</sub> and STV<sub>4</sub> and deeper Q<sub>1</sub> and V<sub>4</sub>.

The patient returned home to re-enter the hospital a week later. The pain in the chest had grown steadily worse. It began in the low left posterior chest and radiated anteriorly beneath the rib margins. There was no cough or sputum. The dysphagia had become much worse, and he was able to take only liquid foods. The blood pressure was 100 systolic, 70 diastolic. He suddenly vomited greenish fluid, began to sweat profusely, complained of weakness but no pain, began to breathe rapidly and died within a few seconds.

#### DIFFERENTIAL DIAGNOSIS

DR DANIEL S ELLIS It seems to me that up to the time of the second admission we have a fairly clear picture of a patient who had some vascular disturbance in the lower extremities and probably had pulmonary infarction and for some reason developed cardiospasm of the esophagus. The second admission puzzles me a great deal, and I do not know where I am going to end up at this point.

May we see the x-ray films? Is there any evidence of pulmonary infarct or anything that might be called pulmonary infarct in the first chest film?

DR STANLEY M WYMAN There are a few scars—linear bands of density. If this represents pulmonary infarct, it is only the old residual scar. In general, the picture is that of a chronically emphysematous chest, with signs of diffuse fibrosis out to the periphery in both lung fields. The dia-

phragm is low in position, the heart shadow is enlarged toward the left, probably owing to left ventricular hypertrophy. The aorta is quite tortuous for a man of fifty-one. The barium-filled esophagus can be seen through the heart shadow, it can be seen much better in the lateral view of the chest, which shows this area of narrowing just below the carina. On several spot films taken at this time there is a suggestion of a small crater centrally, it is seen on all the films. There is a characteristic shelf formation, and there seems to be a suggestion of a little nodularity in the upper border of the area. The area extends in all about 2 cm. The films taken a month later again show essentially the same picture, but the crater can no longer be so well identified on the large films. However, on the small films, again, there may be a crater in this area. The next film of the chest taken about three or four months after the original examination again shows a rather considerably enlarged heart but no definite change in the pulmonary pattern. Three months later there is an increase in linear shadows in both lung fields, which may be partly due to technic, though it seems a little more than artifact. The last film taken eight days later shows considerable density extending upward into both lung fields and radiating from the region of the hilus.

DR ELLIS Was that taken before he died?

DR WYMAN I do not know, but I think so.

DR ELLIS Is the aorta enlarged in the last film?

DR WYMAN It is definitely tortuous.

DR ELLIS How about the aorta in these films? Is there any dilatation there?

DR WYMAN I cannot say on these films, the reason being that I can see only the right border of the aorta in the posteroanterior view, the left border is hidden by the mediastinum. In the films taken to project the aorta away from the surrounding structures the aorta does not seem wide, but it is definitely tortuous.

DR ELLIS Is there any evidence of destruction of the vertebrae anywhere?

DR WYMAN I do not see it on these films nor did I on some other films of the spine that I have not shown.

DR ELLIS I think I will have to attack this from the end of the story and work toward the beginning. The one thing I am certain of is that a large vessel ruptured and that death was due to hemorrhage.

The presenting complaints at the time of entry to the other hospital were crampy pain in the legs and pain in the back and chest, and at that time he was known to have coughed up bloody sputum. Over a period of hospitalization there he developed the gastrointestinal complaints and dysphagia. Without any question it was believed that the chest pain and the bloody sputum were due to pulmonary infarcts because the femoral veins were tied. At no time was mention made of any swelling of either leg or anything more than pain and some stiff-

6.7 gm per 100 cc The urine gave a ++ test for albumin, and the sediment contained 10 to 12 white cells and 3 to 4 red cells per high-power field An x-ray film of the chest showed the left side obscured by homogeneous density The heart and mediastinum were displaced to the right

The patient was oriented but unco-operative and incontinent On the second hospital day 300 cc of thick, purulent nonputrid material mixed with old blood was aspirated from the sixth and eighth interspaces posteriorly and the sixth interspace in the axillary line A smear of this fluid showed pus cells and clumps of gram-positive cocci This procedure was repeated on the fourth and seventh hospital days with similar findings The material was negative for tumor cells and grew out abundant colonies of *Staphylococcus aureus* and nonhemolytic streptococci The temperature varied from 99 to 102°F The patient received 192,000 units of penicillin daily On the eighth hospital day a rib resection was done The pleura was very thick but no large cavity was encountered His condition was unchanged until the third postoperative day when he was found apneic and in shock, and attempts at resuscitation were ineffectual

#### DIFFERENTIAL DIAGNOSIS

DR W WILSON SCHIER This is the story of a lawyer who developed cough and fever following a prefrontal lobotomy We do not know the details of the operation or the anesthesia used or how long after the operation the symptoms appeared but presumably shortly after it At that time an x-ray film of the chest was reported as showing patchy mottling

The patient received a course of penicillin, said to be intensive but for how long or how much was received is not known This pulmonary process progressed until two months later another x-ray film showed extensive consolidation in the upper half of the left lung, with a 4-cm excavation on the second anterior rib and also, homogeneous density of the left-lung field May we see the films at this point

DR JAMES J McCORT We have the chest films taken on admission to this hospital A homogeneous density obscures the entire left thorax so that details of the underlying left lung cannot be made out The mediastinum shows a marked shift to the right The left leaf of the diaphragm is not seen, but the

gas-filled fundus of the stomach is seen to be higher than normal, which indicates that the left leaf of the diaphragm is very high No evidence of bone erosion or destruction is detectable in the ribs

DR SCHIER On admission this man showed evidence of long-existent emaciation and avitaminosis The swelling of the face and eyes may have been due to partial obstruction of the venous drainage of the upper part of the body

We are given a single total protein value, 6.7 gm per 100 cc He may possibly have had a low albumin We do not know whether he was hospitalized in a mental hospital or not, but we do know that the tuberculosis rate in mental hospitals is higher than it is in the average population

Two other thoughts come to mind Electric shock therapy was given two years before lobotomy Lung abscesses have been described following shock therapy The second possibility is primary carcinoma of the lung with cerebral metastases giving rise to personality change The long course of events, however makes these two diagnoses unlikely

The swelling of the face and eyes may also have been due to chronic nephritis, resulting from focal emboli or focal nephritis in the kidneys The physical signs are consistent with cavity at the left base and fluid in the left pleural space

The laboratory data are compatible with an infectious process of long standing and associated anemia The urinary findings are interesting because of the possibility they raise of metastatic abscesses in the kidneys The question of a palpable liver edge might be the result of multiple hepatic abscesses Also sepsis of this long standing might have given rise to amyloid disease The description of the sputum is lacking We do not know whether it was foul or bloody and whether acid-fast organisms were seen

I think that this man had a lung abscess primarily I do not believe he had a carcinoma of the lung Whether he had empyema with broncho-pleural fistula, I do not know Visibility of the abscess especially on the upper half of the left lung favors carcinoma or a tuberculous process rather than aspiration abscess

The fact that the fluid aspirated was nonputrid merely means that no putrefying organisms were present

The deviation of the trachea to the right is less in favor of tuberculosis Actinomycosis must be considered in a septic process of this duration Lack

## PATHOLOGICAL DISCUSSION

DR MALLORY The very widespread, bizarre distribution of pain was suggestive of dissecting aneurysm to me when I read the story over. I do not believe we have an adequate explanation for the pain because the patient did not have a dissecting aneurysm nor did we find anything else to account for it. He had a markedly sclerotic aorta for a man of only fifty-one, if he gave his age correctly, but there were no ulcerations or aneurysmal formation. He had a greatly hypertrophied heart, which weighed 720 gm. There were occlusions in both left descending and right coronary arteries, and there was a large area of infarction involving the lower third of the left ventricle and of the interventricular septum. The complete surprise was the presence of acute bacterial endocarditis of the mitral valve. There is nothing in the history that would remotely have led one to think of such a diagnosis. The obstruction of the coronary arteries could have been due to embolism from the cardiac vegetations or to ordinary thrombosis secondary to atheroma because he had severe atheromatous changes. I favor the latter. The progressive changes in the lungs, which Dr Wyman has brought out in this series of x-ray films, we did explain. There was extensive lipoid pneumonia of the type seen following aspiration of liquid paraffin. It was sufficiently chronic to have produced much pulmonary fibrosis. This is a fairly common pulmonary complication in patients who have difficulty in swallowing, whether it is due to organic obstruction or to muscular weakness.

DR JAMES HEYL About how old was the process?

DR MALLORY It was a matter of months, possibly longer. It is not uncommon, in some of these cases, to see some of the oil transported to other parts of the body. We see it frequently in the spleen. This is the first time I have ever seen it in the liver. Many vacuolated phagocytes were present in the portal areas and sometimes within the lobules. The esophagus showed perfectly normal mucosa except for a small area of ulceration, but the sub-epithelial tissue was greatly thickened and fibrous with some infiltration of monocytes and plasma cells.

DR ALFRED KRANES Was there any gastric mucosa?

DR MALLORY None was visible, and I believe the lesion was too high to make such a possibility likely.

DR ELLIS What about the legs? Did the patient have thrombophlebitis?

DR MALLORY We have no evidence. They showed nothing externally. There were no pulmonary infarcts.

A PHYSICIAN What did he die of?

DR MALLORY Acute heart failure.

DR KRANES How do you account for the sudden change after eight days if the coronary-artery disease had been present a long time?

DR MALLORY We do not know how long the bacterial endocarditis may have been present or how much pulmonary insufficiency contributed to the fatal outcome.

## CASE 34422

## PRESENTATION OF CASE

A forty-three-year-old lawyer was admitted to the hospital because of persistent cough and fever. The cough and fever began five months before admission, following a prefrontal lobotomy. X-ray studies showed patchy mottling of the left-upper-lung field. There was little response to penicillin, and three months before admission another x-ray film showed extensive consolidation in the upper half of the left lung with a central, clear area 4 cm in diameter at the level of the second anterior rib. The mediastinum was displaced to the right. A week later multiple cavities could be seen in the left-upper-lung field. The patient continued to run a fever and leukocytosis and developed a marked anemia despite two blood transfusions.

Three years before admission the patient became depressed, with suicidal tendencies. Electric shock therapy resulted in improvement for a year, but symptoms recurred and a frontal lobotomy was performed.

Physical examination revealed an emaciated man with moderate edema of the face, eyes and sacrum. There were patchy areas of scaling and hyperkeratosis over the extensor surfaces of the extremities. The tongue was smooth and glossy. The trachea was shifted to the right. Over the upper half of the left lung there were dullness and bronchial breathing, with flatness and absence of tactile fremitus and breath sounds in the lower half. The liver edge was questionably palpable.

Examination of the blood revealed a white-cell count of 18,200, with 89 per cent neutrophils, and a hemoglobin of 11.5 gm. The total protein was

## GREATER BOSTON COMMUNITY FUND

NEXT week the Greater Boston Community Fund begins its annual drive to ensure continued operation of more than three hundred Red Feather agencies. The campaign, which will last for five weeks, will as usual ask the support of all sections of the community.

This year's goal of \$6,950,000 is estimated as the absolute minimum that will enable the Red Feather agencies to operate on the same scale as last year. The needs are stated to be greater than ever before. All the eight main fields of service—child care, family service, aid to the handicapped, visiting-nurse and other health agencies, hospitals, service for the aged, youth organizations and neighborhood

houses for young and old—are essential to the well-being of the community, and all depend on the contributions made during the campaign. The USO, which has been reactivated at the request of Secretary of Defense Forrestal, will depend in large part on the support given to the Fund.

Doctors daily contribute medical service to many of the Red Feather agencies, but they are asked also to respond as generously as possible to the appeal for financial help made during the campaign. Physicians connected with hospitals will be approached by a chairman or a vice-chairman on the hospital staff and individual practitioners by the regular volunteer workers either at home or in the office.

There is no question that the enormous service rendered by the Red Feather agencies must continue. This voluntary means of helping others to help themselves represents the American way of life at its best. Doctors are urged to give the campaign all possible support. The Red Feather, symbol of both the worker and the giver, should be proudly worn by physicians as indicating their dual role in the community.

## ARTERIAL TRANSPLANTS

THE investigations into the use of arterial grafts presented elsewhere in this issue of the *Journal* by Gross and his associates deserve particular mention. Their importance is measured in terms of the recent development of cardiovascular surgery to which Gross himself has made such outstanding contributions and in which the necessity for bridging gaps in the arterial system is so urgent, further, the possibility that arterial transplants might be made constantly available for these needs has been suggested by the development of methods of preserving blood, corneal transplants and bone tissue.

These careful studies on the possibilities of arterial grafts have proceeded in orderly fashion. First it was determined using the abdominal aortas of dogs as test material that fresh segments of artery could be transplanted from a donor to a recipient animal, that the recipient animal could survive the operation and that the transplanted tissue could be incorporated into the arterial sys-

of response to penicillin favors both actinomycosis and tuberculosis as possible etiologic agents. Response to surgery was no better than to penicillin.

The terminal episode may have been the result of flooding of the right lung with secretions from the left lung and development of a bronchopleural fistula. Massive pulmonary embolus and brain abscess are other possibilities. My final diagnosis is lung abscess, following the original operation, with terminal bacteremia and septic emboli in the kidneys and possibly in the brain. I cannot rule out primary lung tumor, tuberculosis or primary actinomycotic infection.

DR McCORT: The high left leaf of the diaphragm is hard to explain. One wonders about phrenic paralysis, favoring tumor. This could have been definitely determined by fluoroscopy, which unfortunately was not done.

A PHYSICIAN: Empyema of long standing might also explain it.

DR McCORT: The mediastinum is displaced to the right side. I am not sure that the left leaf of the diaphragm should be elevated if there is fluid under tension above it.

#### CLINICAL DIAGNOSIS

Lung abscess, with empyema

#### DR SCHIER'S DIAGNOSES

Lung abscess

Terminal bacteremia

Septic emboli in kidneys and possibly in brain

#### ANATOMICAL DIAGNOSES

*Carcinoma of left bronchus, with extension into mediastinum and metastases to cervical, medias-*

*tinal and abdominal lymph nodes, liver and right kidney*

*Pneumonitis, with abscess formation*

Thrombosis of left jugular and subclavian veins

Bicuspid aortic valve

#### PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY: The diagnosis on the wards was the same as Dr Schier's — primary lung abscess with empyema. At autopsy we found a lung abscess but not primary; it was distal to a tumor of the left bronchus that had grown to fill a considerable portion of the left lung. There were many foci of necrotic tumor and secondary abscess formation beyond the point of obstruction. The tumor had metastasized to the liver and kidney but only with relatively few and small metastases. The liver was not enlarged. The tumor had invaded it and expanded locally through the pleura and involved the pericardium. The phrenic nerve was not specifically sought for but in all probability was involved by the tumor, since it spread through the pleura to the pericardium. A coincidental finding, evidently of no importance, was a congenital bicuspid aortic valve.

We did not have permission to examine the brain, but I think it is rather improbable, as Dr Schier said, that the cerebral manifestations were due to metastases. I think they were probably due to psychosis.

A PHYSICIAN: Did the kidney show anything other than metastases?

DR MALLORY: There was slight bilateral hydro-nephrosis and a very slight degree of chronic pyelonephritis.

---

**Correction** On Page 482, in the last sentence of Dr Means's discussion of Case 34391, which appeared in the September 23 issue of the *Journal*, the word "heart" was erroneously used for "leg veins." This should have read as follows:

Taking all the cases of pulmonary embolism with infarction, what percentage would you say come from the leg veins?

DR MALLORY: What would your opinion be, Dr Castleman?

DR BENJAMIN CASTLEMAN: Probably about 95 per cent.

for the solving of complicated statistical problems, but their readiness to give aid does not relieve the clinical investigator of the need to familiarize himself with the basic principles and general application of the statistical method. A brief and admirably lucid book, written specifically for those who require no more than this, is that by Hill\*. Heretofore, many clinical investigators have handicapped themselves by failing to familiarize themselves with works such as this, and the current trend toward routine appropriate statistical analysis of clinical research data is a constructive, and probably an overdue, development.

### ARMY MEDICAL TRAINING PROGRAM

THE Army Medical Corps has extended to November 1 its time limit for medical-school graduates to apply for commissions under the Civilian Resident and Intern Training Program. This opportunity must impress itself upon all recent graduates in view of the increased need for medical personnel to care for the nation's expanding forces, and the obvious intention of the authorities to fill the need.

Under the program, according to a recent release from the Office of the Surgeon General, selected individuals serve out their internships and residencies in civilian hospitals of their choice — interns as first lieutenants of the Medical Reserve Corps and residents with the same rank in the Regular Army Medical Corps. Both receive full pay and allowances of their rank with \$100 a month in addition as a professional volunteer bonus.

Upon completion of a year's training interns must apply for Regular Army commissions and may qualify for resident training. Residents, upon concurrence of the hospital, may continue their training with a view to qualifying for specialty courses leading to certification by American Specialty Boards. The Graduate Training Program may here continue as the Career Management Program under which medical officers are assured of continuation in their specialties during Army service, except in the case of administrative or staff careers. Participating officers are expected to serve a year of active duty for each year of training they receive.

tem of the host and could perform the function for which it was intended. Here it became evident, as might be expected, that the greater the delay between donor and recipient, the less were the chances of tissue survival.

The development of a method of tissue preservation came next, preservation by freezing was attempted, and it was demonstrated that arterial tissue cannot survive this process. The next experiment consisted of the storing of aortic segments in an electrolyte solution to which had been added glucose, dog serum, a buffer, penicillin and streptomycin and a phenol-red indicator. Segments so preserved and refrigerated at a temperature between 1 and 4°C remained viable for over a month and were transplanted into recipient animals with a high percentage of successful "takes."

The culminating step, toward which all animal experimentation must be directed, has been its application to the human being. Segments of arteries removed from recent victims of automobile accidents were preserved and stored in the manner described above. Nine such grafts have been used to bridge gaps between the aortic and pulmonary arterial systems in the tetralogy of Fallot, with 7 successful results, 2 patients died soon after operation. Furthermore, 3 grafts have been used without a failure in surgical correction of coarctation of the thoracic aorta.

As medical science has developed blood banks, eye banks and bone banks, so the way now seems clear for the establishment of artery banks. In the great human repair shop that the modern hospital has become, the spare-parts department assumes increasing importance.

## THE PHYSICIAN AND THE STATISTICAL METHOD

MANY physicians, particularly those who do clinical research, appear to regard the statistical method as the exclusive property of their colleagues in public health or laboratory research. They often dismiss the exact technic somewhat defensively, by repeating the time-worn statement that anything can be proved by statistics. In recent years, however, more and more clinical in-

vestigators are found to be using statistical tests to examine their data, and it may be that the older view needs drastic revision.

The author of a case report hardly needs to turn to the statistical method to support his presentation, but authors dealing with groups of cases should consider the advantages of proper statistical evaluation of their data. The initial planning of any such study is immeasurably benefited by consideration of certain statistical principles such as those dealing with sampling. The results of well planned work can be displayed to much greater advantage if they are treated statistically than if they are not. For example, an average figure is much more meaningful if the variation around the average is presented along with it. One of the most frequent research devices is to compare treated and untreated groups of cases, and, too frequently, one finds the investigator basing his conclusions on a difference that is more apparent than real. Relatively simple statistical techniques for testing the significance of such differences are available, and by the proper application of these tests it can readily be determined whether the result is truly significant or whether it is a chance one. The tests are useful not only in evaluating one's own results but also in determining whether those published by other workers are significant, merely suggestive or clearly unreliable.

One may argue that plain horse sense can do the same thing and that there is no need to resort to a mere sophistic, mathematical device for the purpose. The statistical method, however, properly applied, is in fact more than this and might well be defined as horse sense quantitated. It will if judiciously used, keep the overenthusiastic researcher from drawing unjustified conclusions and enable the overcautious investigator to express with confidence the full meaning of his findings. All this can and should be achieved with due consideration of the confusion that results to the reader if a writer adorns his treatise with countless standard deviations, chi squares, T-tests and other statistical symbols.

Few physicians have the time, and perhaps not a great many have the ability, to become master statisticians. Trained statisticians are available

or the solving of complicated statistical problems, but their readiness to give aid does not relieve the clinical investigator of the need to familiarize himself with the basic principles and general application of the statistical method. A brief and admirably lucid book, written specifically for those who require no more than this is that by Hill.\* Heretofore, many clinical investigators have handicapped themselves by failing to familiarize themselves with works such as this, and the current trend toward routine, appropriate statistical analysis of clinical research data is a constructive, and probably an overdue, development.

### ARMY MEDICAL TRAINING PROGRAM

THE Army Medical Corps has extended to November 1 its time limit for medical-school graduates to apply for commissions under the Civilian Resident and Intern Training Program. This opportunity must impress itself upon all recent graduates in view of the increased need for medical personnel to care for the nation's expanding forces, and the obvious intention of the authorities to fill the need.

Under the program, according to a recent release from the Office of the Surgeon General, selected individuals serve out their internships and residencies in civilian hospitals of their choice — interns as first lieutenants of the Medical Reserve Corps and residents with the same rank in the Regular Army Medical Corps. Both receive full pay and allowances of their rank with \$100 a month in addition as a professional volunteer bonus.

Upon completion of a year's training interns must apply for Regular Army commissions and may qualify for resident training. Residents, upon concurrence of the hospital, may continue their training with a view to qualifying for specialty courses leading to certification by American Specialty Boards. The Graduate Training Program may here continue as the Career Management Program under which medical officers are assured of continuation in their specialties during Army service, except in the case of administrative or staff careers. Participating officers are expected to serve a year of active duty for each year of training they receive.

†Six year median.

## COMMENT

Diseases with an incidence above the seven-year median included chicken pox, diphtheria, dog bite, measles, mumps and poliomyelitis

Diseases with an incidence below the seven-year median included salmonellosis, scarlet fever, undulant fever and whooping cough

A number of cases reported as meningitis, undetermined, poliomyelitis and lymphocytic choriomeningitis had the same clinical and spinal-fluid findings

Measles had the highest incidence for August since 1916 Mumps had the highest August incidence since it was made reportable Whooping cough continues to be reported at the lowest level since 1915

#### GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Arlington, 2, Boston 10, Chicopee, 1, Everett, 1, Natick, 2, Revere, 1, Somerville, 1, total, 18

Dysentery, amebic, was reported from Newton, 2, total, 2  
Dysentery, bacillary, was reported from Chelsea, 1, Waltham, 1, Worcester, 10, total, 12

Lymphocytic choriomeningitis was reported from Fitchburg, 4, Malden, 1, total, 5

Malaria was reported from Cambridge, 1, total, 1

Meningitis, meningococcal, was reported from Boston, 2, Framingham, 1, Holyoke, 1, Springfield, 1, Worcester, 1, total, 6

Meningitis, Pfeiffer-bacillus, was reported from Auburn, 1, total, 1

Meningitis, other forms, was reported from Haverhill, 1, Holden, 1, total, 2

Meningitis, undetermined, was reported from Brockton, 1, Leominster, 4, Melrose, 1, Worcester, 1, total, 7

Poliomyelitis was reported from Abington, 1, Adams, 1, Andover, 1, Ayer, 1, Becket, 1, Boston, 1, Brookline, 2, Carver, 1, Danvers, 2, Dracut, 1, Gloucester, 3, Groveland, 2, Ipswich, 1, Lincoln, 1, Middleboro, 1, New Bedford, 1, Newton, 3, Northampton, 1, Norwood, 1, Peabody, 1, Quincy, 1, Revere, 1, Salem, 3, Springfield, 3, Swampscott, 1, Waltham, 2, Watertown, 2, Wellesley, 1, West Boston, 17, West Bridgewater, 1, West Stockbridge, 1, Weston, 2, Whitman, 1, Winthrop, 1, Worcester, 5, total, 69

Salmonellosis was reported from Lowell, 2, Malden, 1, Methuen, 2, Norfolk, 6, Somerville, 1, total, 12

Septic sore throat was reported from Fall River, 1, Rutland, 1, total, 2

Tetanus was reported from Lexington 1, Newton, 1, total 2

Trichinosis was reported from Fall River, 3, Lawrence, 1, Swansea, 2, Waltham, 1, total, 7

Typhoid fever was reported from Beverly, 1, Boston, 1, Gardner, 1, Lowell, 1, New Bedford, 1, Somerset, 1, total, 6

Undulant fever was reported from Malden, 1, Warren, 1, total, 2

## BLUE CROSS — BLUE SHIELD

### THE BLUE SHIELD DOLLAR

Associated Medical Care Plans, in a recent release, presents an analysis of payments to physicians for benefits provided under the average surgical type of subscriber contract

Four types of surgical procedure — appendectomies, tonsillectomies and obstetric and gynecologic operations — account for approximately sixty cents of every dollar paid to physicians The next twenty-five cents goes to pay for approximately seventy surgical procedures Payments for x-ray and anesthesia are on the increase, owing perhaps to an increasing number of physicians entering these fields

Female subscribers cost about three times as much for surgical benefits as do male subscribers, with female dependents only slightly less expensive While these costs are due largely to obstetrics and

gynecology, female costs in general surgery are also above the average, principally on account of breast operations

Male dependents cost more than female dependents, because of herniotomies, circumcisions, fractures and dislocations, boys breaking almost exactly twice as many bones as their sisters do

## BOOK REVIEW

*Heart A physiologic and clinical study of cardiovascular diseases* By Aldo A Luisada, M D With a foreword by Herrman L Blumgart, M D 4°, cloth, 653 pp, with 352 illustrations Baltimore The Williams and Wilkins Company, 1948 \$10.00

The disrupting effects of two world wars upon European medicine have accelerated the development of the United States as the international center of medical science. The turbulence of the political situation led in the past twenty years to the emigration of many outstanding foreign physicians Dr Luisada brought to this country some years ago the knowledge of the Italian school of medicine. It is to the benefit of American physicians that books by foreign investigators be available in English, since Americans are notoriously unwilling, or unable, to utilize material in other languages

This book is an attempt to cover the field of cardiovascular diseases, a task, as Dr Blumgart says in the foreword, that is "herculean" There are thirty-three chapters followed by a section on diets, and one on prescriptions, and inserted at the end there is a folded table of "summary of treatment in cardiovascular emergencies"

There are as many schemes of classification of cardiovascular diseases as there are authors — this one avoids the etiologic, except when correlated with the fundamental anatomicoclinical syndromes on which the classification is based The historical data and extensive bibliography make the book valuable as a reference, particularly in its use of eponyms, many of which, though unfamiliar, may help in establishing priority in description of certain syndromes

The physiologic approach to cardiovascular problems has advantages, and the schematic illustrations and descriptions of experiments with models should be useful to students

Anatomy is well covered with many figures The chapter on "Normal Functions" is followed by those on "Clinical Study" and "Technical Study" Newer methods of investigation with radioactive isotopes and cardiac catheterization will undoubtedly make much of the latter chapter of his tonical interest only, within a few years, and such procedures as diagnostic pneumomediastinum seem already so The section of phonocardiography is extensive and presents the author's notable experience in this relatively new field, and gives a practical background for those using this technique

The causes of cardiovascular diseases are considered, and this chapter precedes the descriptions of rheumatic disease, endocardial diseases, valvular defects of the left and right sides of the heart, simple shunts and complex malformations

The disturbances of rate and rhythm of the heart are illustrated with diagrams, electrocardiograms and phonocardiograms and the clinical descriptions, tests, diagnosis and treatment combined with these objective records

Diseases of the myocardium, metabolic and endocrine diseases and coronary-artery diseases are given separate chapters. Although it is obvious that detailed consideration of these conditions cannot be given in a single volume covering all cardiovascular disease, it is commendable that so much of the literature has been noted and so many procedures mentioned that can be studied in the original references.

Pericardial diseases are given twenty-seven pages, and diseases of the aorta twenty-six, whereas hypertension is covered in twelve pages. This reflects the special interests and investigations of the author, as noted in his preface. In the treatment of hypertension sodium restriction is referred to only by the statement that a "reduction of salt may be indicated." The rice diet is not mentioned. Surgical treatment is allotted less than half a page.

The final chapters cover cor pulmonale, hypotension, diseases of the arteries and veins, borderline syndromes, complex heart diseases, paroxysmal dyspnea, heart failure, the cardiac patient as an obstetric and surgical risk, drugs, the management of the cardiac patient and medical treatment of common cardiac conditions.

The book is well printed on high-grade paper in the two column to a page method that has become popular. It is so designed as to be useful to medical students, practitioners, cardiovascular specialists and reference libraries.

## BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

*Surgical Applied Anatomy*. By Sir Frederick Treves, Bart. Eleventh edition, revised by Lambart Rogers, MSc, FRCS, FRCSSE, FRACS, FACS, professor of surgery, University of Wales, and member of the Court of Examiners, Royal College of Surgeons of England. 12°, cloth, 560 pp., with 192 illustrations, including 66 in color. Philadelphia: Lea and Febiger, 1947. \$6.00.

This manual has enjoyed a long and honorable career. It first appeared in 1883, and after the death of Sir Frederick Treves was continued in succession by Sir Arthur Keith, Professor C. C. Choyce and Professor Rogers. Despite limitations of time the present edition has been revised radically. Composed and printed in Great Britain and bound in the United States, the book is well published. It was originally intended for students of surgery as a manual of applied anatomy. It should prove of value to surgeons as a quick reference source.

*The Yearbook of Psychoanalysis*. Volume 3, 1947. Managing editor, Sándor Lóran, MD 8°, cloth, 309 pp. New York: International Universities Press, 1948. \$7.50.

In this serial volume are brought together for convenient reference twenty papers, originally published in a number of different periodicals. The paper of A. Garma on psychoanalytic investigations in melancholias and other types of depressions was published originally in Italian but has been translated into English for this publication. The volume is well published and should be in all large medical libraries and in psychiatric collections.

*Mar Weather Sun*. By William F. Petersen, MD 8°, cloth, 462 pp., with 294 illustrations. Springfield, Illinois: Charles C. Thomas, 1947. \$10.00.

Dr. Petersen presents a detailed study of man in relation to the air mass in which he lives. The author summarizes the work upon the subject during the decades 1920-1930 and 1930-1940. The studies of the first decade demonstrated that the weather was an important factor in the life of man, but that progress was retarded because of the lack of encouragement from medical and scientific circles. In the second decade progress was advanced, and observations were made relating to the reaction of the normal and the sick person to weather changes. Dr. Petersen summarizes the results as follows: conditioning by the weather, whether the subject is exposed directly or sheltered in the home or hospital, the reflection

of the weather in the precipitation of diverse clinical pictures, the conditioning of genetic trends during the earliest stages of development, the conditioning of the mental reaction of the normal, and of the abnormal reaction in the psychopathic person, and the obvious reflection of the weather in births and deaths in the population at large. In 1940 the exceptional opportunity of studying daily a set of adult triplets over a period of six weeks was presented to the author, and the results of these comprehensive studies demonstrated that genetically like persons react similarly to the meteorologic environment in which they exist. Previously studies were made on isolated persons. Of importance in these studies of the triplets was the demonstration of the magnitude of the biochemical and biophysical reactions. The book is divided into five parts: the first, comprising one hundred and twenty-one pages, gives in detail the observations on the triplets; the second describes the reaction of the population in births, deaths, suicides, twinning and psychopathic admissions, based on the results of the triplet observations; the third considers man as a cosmic resonator and discusses cosmic, weather and organic rhythms, organic cycles, blood reaction, vital indexes of scarlet fever, epilepsy and death, and the trends of 1930 to 1943 applied to longer rhythms than one year; the fourth, entitled "The symphony of sun and man," considers the possible integration of human reactions and solar rhythm of long range, including the discussion of the sun and the sunspot cycle, epidemics, death, blood reaction, modification of genetic trends of conceptions, weight and length ratio of the newborn and twinning, and genius; the fifth, "The great year," is a study of the Egyptian period from 5400 B.C. to 1240 A.D., which develops the probability of long-range trends in cultures and civilizations, and their significance for the present and the future. Appended to the text are detailed individual charts of the observations on the triplets. Indexes of authors, subjects and illustrations conclude the volume. Some of the part headings are fanciful and not indicative of the contents of the chapters. There is a large amount of statistical material, including charts and curves throughout the text. The publisher has solved a difficult matter in makeup and has produced a well published volume. The book should be in all public-health collections.

*Psychosomatic Medicine: A study of the sick society*. By James L. Halliday, MD, DPH 8°, cloth, 277 pp. New York: W. W. Norton & Company, Inc., 1948. \$3.50.

This study is based on the application of psychosomatic medicine to the illnesses of communities and social groups. The author puts forward the thesis that groups may become physically ill and become sick populations, characterized by high morbidity and mortality rates, owing to mass malnutrition, infectious diseases, infestations and so forth. Likewise, a group has psychologic or social needs, and if these needs are not satisfied its psychologic or social health declines and the group becomes a sick society, he calls the medical approach to this sick society psychosocial medicine. The author would have preferred the term "social medicine" but was debarred from its use by the pre-emption of the term by others. The material in the book is largely derived from original researches—clinical, statistical and methodologic—that employed the psychosomatic approach and extended over a period of ten years. The text is divided into three main divisions: medical logic, in which some principles of etiology are discussed, psychosomatic medicine, subdivided into four chapters, in which the concept and incidence of psychosomatic affections, psychosomatic medicine and the problems of chronic and recurring illness, and the ontogenetic theory and psychosomatic affections are considered; the sick society, in six chapters, which discusses epidemiology, a declining birth rate and psychologic health, psychosocial medicine, the case of Britain as a sick society, the mining community as a sick society and problems of reintegration, including the social function of medicine and the social functions of politics. In conclusion, the author states that as social sickness is a disease the basic observations upon it are appropriately made in terms of medicine and arranged in familiar medical categories, but that much further field investigation needs to be done, before social therapeutics becomes a subject of medicine in its own right. The text is concluded with an appendix comprising notes on five chapters, including the bodily mechanism of emotion, the significance of a psychosomatic illness, social health and the United States, and the

**AMES COMPANY, INC.**  
ELKHART, INDIANA

incidence of psychosomatic affections in underground miners. A good index concludes the volume. The monograph is well published and should be in all public-health collections.

*You and Your Doctor*. A frank discussion of group medical practice and other modern trends in American medicine. By Benjamin F. Miller, M.D., clinical professor of medicine, George Washington University School of Medicine, and research associate in medicine, National Research Council. 8°, cloth, 183 pp. New York: Whittlesey House, 1948. \$2.75.

In this popular book Dr. Miller analyzes the various aspects of medical practice of the present time, including the status of the general practitioner, the diagnostician, group clinics and the modern hospital. He also discusses freedom from emotional illness, periodic medical checkups, post-mortem examinations, medical education and research, and interstate medical care. On the national level is noted the need of an adequate disaster service preferably operated by a federal agency. Under the heading "Who Should Administer National Medical Care?" Dr. Miller considers impartially the agencies best able to promote and operate a national plan, and although a member of the American Medical Association and favoring it in his analysis, he is convinced that the United States Public Health Service is at present in the best position to operate a plan co-ordinating preventive medicine, curative or clinical medicine and medical research, the three major essentials of such a national plan. If the Public Health Service cannot assume the promotion and operation of a national plan, Dr. Miller suggests that a special federal agency be established for that purpose. The book is well published, except that it lacks an index. The volume should be in all public-health collections.

*Textbook of Gynecology*. By Emil Novak, M.D., assistant professor of gynecology, Johns Hopkins University School of Medicine, and gynecologist, Bon Secours and St. Agnes Hospitals, Baltimore. Third edition. 8°, cloth, 742 pp., with 484 illustrations. Baltimore: The Williams and Wilkins Company, 1948. \$8.00.

Dr. Novak has brought up to date this third edition of his standard textbook on gynecology. A considerable number of illustrations, some in color, have been added. Dr. H. S. Everett has revised his chapter on female urological conditions of special interest to the gynecologist. A list of selected references is appended to each chapter, and there is a good index. The publishing is well done. The book should be in all medical libraries and in the private collections of gynecologists and physicians interested in the subject.

*Clinical Toxicology*. By Clinton H. Tienes, M.D., Ph.D., professor of pharmacology and head of the Department of Pharmacology and Toxicology, School of Medicine, University of Southern California, Los Angeles, an attending pathologist (toxicology), Los Angeles County Hospital, and Thomas J. Haley, Ph.D. Second edition. 12°, cloth, 373 pp. Philadelphia: Lea and Febiger, 1948. \$3.50.

The second edition of this popular manual for students and general practitioners has been thoroughly revised and enlarged to the extent that the text has been entirely reset and printed from new type. Sections have been added on dicoumarol, heparin, thiouracil, DDT, gold, BAL and streptomycin. Material has also been added on proteins, amino acids and vitamins in the treatment and prevention of poisoning. The section on the chemical identification of poisons has been enlarged to include tables, comparing color and other reactions, as well as new tests for arsenic, the barbiturates, cyanide and the sulfonamides. The nomenclature has been brought into line with the thirteenth edition of *United States Pharmacopoeia*, the eighth edition of the *National Formulary* and the 1947 edition of *New and Nonofficial Remedies*. The material is well arranged, and the volume is well published. The manual should prove useful as a reference source to libraries and to all persons interested in the subject.

*Organic Form and Related Biological Problems*. By Samuel J. Holmes. 8°, cloth, 169 pp. Berkeley: University of California Press, 1948. \$5.00.

This small volume practically consists of thirteen separate essays on closely related subjects in biology. The short essay on the regeneration of blood and its bearing on morphogenic theory and the long one on cancer as a biologic problem are

of direct medical significance. In the essay on cancer the author presents a comprehensive survey of the current theories on the causation of cancer, with emphasis on genetic factors. Likewise of interest is the article on autocatalytic enzymes and the origin of life. Six of the articles were published previously in scientific periodicals. A bibliography arranged by chapters follows the text, and an index concludes the volume. The text is well written, and although it makes admittedly difficult reading is recommended for all medical libraries and, naturally, for biologic collections. It should be available to all persons interested in carcinogenesis. The book is well published.

## NOTICES

### ANNOUNCEMENTS

Dr. Jackson M. Thomas announces the opening of an office at 311 Beacon Street, Boston, for the practice of psychiatry.

Dr. James L. Tullis announces the opening of an office at 1101 Beacon Street, Brookline, for the practice of internal medicine and hematology.

### MASSACHUSETTS MEDICO-LEGAL SOCIETY

The fall, winter and spring meetings of the Massachusetts Medico-Legal Society will be held, respectively, on Wednesday, October 20, 1948, in the Magrath Library, Building E, Harvard Medical School, Boston, on Wednesday, February 9, 1949, in the Magrath Library, Building E, Harvard Medical School, Boston, and on Wednesday, May 25, 1949, in the Worcester Memorial Auditorium, Worcester. The program for the fall meeting at 2:30 p.m. on October 20 is as follows:

#### Business Meeting

Air Embolism as a Complication of Abortion. Leroy T. Stokes, M.D., and Richard Ford, M.D.

Acute Isolated Myocarditis. David Dow, M.D., Daniel J. Kiley, M.D., and Michael Luongo, M.D.

Unexpected Death from Ben-ben Heart Disease. Walter W. Jetter, M.D.

Suicidal Gunshot Injury. James H. McCann, M.D., and Russell S. Fisher, M.D.

#### Collation

The following amendment to the by-laws, as proposed by the Standing Committee, will be considered:

That Article 1, Paragraph 2, of the by-laws be amended by the addition of the words "or honorary," so as to read as follows: "The Society may, at any stated meeting, elect to associate or honorary membership such persons distinguished in medical, legal or technical science as the Standing Committee, acting as a nominating committee, may recommend."

### MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

A meeting of the Middlesex South District Medical Society will be held at the Murphy General Hospital, Waltham, on Wednesday, October 20.

#### PROGRAM

11:30 a.m. Business

12:00 noon Clinical papers "Management of Hyperthyroidism" by Colonel Otto L. Churney, M.C., and Lieutenant Colonel Ralph L. Cox, M.C.

1:00 p.m. Luncheon

Future meetings will be held on December 6, 1948, at Sanders Theater, Cambridge, on January 26, 1949, at Newton-Wellesley Hospital, and on April 20, 1949 (annual meeting), at the Hotel Continental, Cambridge. The December meeting will consist of a symposium on diabetes and will be a joint meeting with Suffolk, Norfolk and Middlesex South in connection with National Diabetes Week.

## HEPATIC COMA\*

### Clinical and Laboratory Observations on Forty Patients

T LYNCH MURPHY, M.D.,† THOMAS C CHALMERS M.D.,‡ RICHARD D ECKHARDT M.D.,§ AND  
CHARLES S DAVIDSON, M.D.¶

BOSTON

**P**ROLONGED coma has been recognized as a frequent terminal event of both acute hepatic necrosis and chronic hepatic fibrosis. Frerichs,<sup>1</sup> in 1860, described the terminal mental changes in patients with acute yellow atrophy and with cirrhosis of the liver.

Cases have occurred to me in which individuals who for a long period have suffered from cirrhosis of the liver have suddenly presented a series of morbid symptoms which are foreign to that disease. They have become unconscious, and have been afterwards seized with noisy delirium, from which they passed to deep coma, and in this state have died. In most cases, slight jaundice made its appearance at the same time.

Frerichs ascribed the mental symptoms to hepatic insufficiency with a decreased output of bile and termed the condition "acholia." Since that time little progress has been made in elucidating the pathological physiology of the condition, and confusion has arisen concerning the clinical features and laboratory findings. In this report attention is drawn to certain of the clinical manifestations, several etiologic factors are suggested, and the use of various therapeutic measures is evaluated.

## MATERIAL

Forty patients were studied who died in coma and who both clinically and pathologically had severe primary liver disease. All were observed during life in the years 1945 and 1946. The coma, which occurred after a variable period of decreasing alert-

ness and which lasted from twelve hours to six days, was the outstanding feature. No cases are included of metastatic liver disease, obstructive biliary-tract disease or massive gastrointestinal hemorrhage severe enough to cause death in shock. A number of otherwise acceptable cases were excluded because a pathological diagnosis was not made.

The cases so selected fall into two groups, equal in number: "uncomplicated" hepatic coma, in which no cause for death other than liver disease was found, and "complicated" hepatic coma, in which the patient had, in addition to severe liver disease, some major complication that may have played an important part in precipitating the coma (Table 1).

Pathological examination consisted of complete autopsy in 29, abdominal exploration and liver biopsy in 8, and punch biopsy of the liver in the remaining 3 cases. In the uncomplicated cases there were 15 of portal cirrhosis, 2 of healed acute yellow atrophy, and 1 each of subacute yellow atrophy, acute yellow atrophy and acute alcoholic hepatitis. In the group with complication there were 17 cases of portal cirrhosis, 2 of healed acute yellow atrophy, and 1 of advanced fatty metamorphosis of the liver.

## RESULTS

### *Uncomplicated Hepatic Coma*

The 20 patients in this group, in whom no cause for death was found other than severe liver disease, were from thirty-five to seventy-two years of age with almost half in the sixth decade, 12 were men. Six of the patients denied the use of any alcohol whereas 3 said that they had consumed no more than an occasional glass of beer or whisky. The remaining 11 admitted consuming at least 2 quarts of beer or a pint of whisky a day for years. Characteristically, they ate poorly when drinking. A summary of the pertinent findings in the history and

## HEPATIC COMA\*

### Clinical and Laboratory Observations on Forty Patients

T LYNCH MURPHY, M.D.,† THOMAS C CHALMERS, M.D.,‡ RICHARD D ECKHARDT, M.D.,§ AND  
CHARLES S DAVIDSON, M.D.¶

BOSTON

**P**ROLONGED coma has been recognized as a frequent terminal event of both acute hepatic necrosis and chronic hepatic fibrosis. Frerichs,<sup>1</sup> in 1860, described the terminal mental changes in patients with acute yellow atrophy and with cirrhosis of the liver.

Cases have occurred to me in which individuals who for a long period have suffered from cirrhosis of the liver have suddenly presented a series of morbid symptoms which are foreign to that disease. They have become unconscious, and have been afterwards seized with noise and delirium, from which they passed to deep coma, and in this state have died. In most cases, slight jaundice made its appearance at the same time.

Frerichs ascribed the mental symptoms to hepatic insufficiency with a decreased output of bile and termed the condition "acholia." Since that time little progress has been made in elucidating the pathological physiology of the condition, and confusion has arisen concerning the clinical features and laboratory findings. In this report attention is drawn to certain of the clinical manifestations, several etiologic factors are suggested, and the use of various therapeutic measures is evaluated.

## MATERIAL

Forty patients were studied who died in coma and who both clinically and pathologically had severe primary liver disease. All were observed during life in the years 1945 and 1946. The coma, which occurred after a variable period of decreasing alert-

ness and which lasted from twelve hours to six days, was the outstanding feature. No cases are included of metastatic liver disease, obstructive biliary-tract disease or massive gastrointestinal hemorrhage severe enough to cause death in shock. A number of otherwise acceptable cases were excluded because a pathological diagnosis was not made.

The cases so selected fall into two groups, equal in number: "uncomplicated" hepatic coma, in which no cause for death other than liver disease was found, and "complicated" hepatic coma, in which the patient had, in addition to severe liver disease, some major complication that may have played an important part in precipitating the coma (Table 1).

Pathological examination consisted of complete autopsy in 29, abdominal exploration and liver biopsy in 8, and punch biopsy of the liver in the remaining 3 cases. In the uncomplicated cases there were 15 of portal cirrhosis, 2 of healed acute yellow atrophy, and 1 each of subacute yellow atrophy, acute yellow atrophy and acute alcoholic hepatitis. In the group with complication there were 17 cases of portal cirrhosis, 2 of healed acute yellow atrophy, and 1 of advanced fatty metamorphosis of the liver.

## RESULTS

### *Uncomplicated Hepatic Coma*

The 20 patients in this group, in whom no cause for death was found other than severe liver disease, were from thirty-five to seventy-two years of age with almost half in the sixth decade, 12 were men. Six of the patients denied the use of any alcohol, whereas 3 said that they had consumed no more than an occasional glass of beer or whisky. The remaining 11 admitted consuming at least 2 quarts of beer or a pint of whisky a day for years. Characteristically, they ate poorly when drinking. A summary of the pertinent findings in the history and

physical examination is presented in Table 2. On admission 5 patients had been jaundiced for from one to eight weeks. Abdominal swelling for one week to eleven months was observed by 13 patients, of whom 4 had had an abdominal paracentesis before admission.

Patients with severe hepatic cirrhosis exhibit to a variable degree alteration in intellectual function and personality. Loss of affect and a defect

senting increasing mental depression to the final stage of deep coma.

Although detailed neurologic examinations were not done, it was obvious that 17 of the patients presented some change in the state of consciousness on admission to the hospital, and in 7 cases mental or neurologic symptoms were the chief reason for admission. Six of these 7 patients admitted with lethargy, stupor or coma were dead

in judgment are usually outstanding. Thus, the jaundiced, pot-bellied cirrhotic patients are usually the jovial clowns of the ward. Many of them leave the hospital time and again, insisting that they are perfectly well in spite of obvious edema, ascites and jaundice. At times, however, they are apathetic or negativistic. Hepatic coma takes its departure from this base line, variable as it is from patient to patient, and develops slowly through phases repre-

within five days, otherwise, there was no correlation between initial mental changes and duration of hospitalization, which ranged from one to a hundred and fifty days. Twelve of the patients in the entire group of 20 died within four days after admission, and only 5 were living after twenty days.

The changes in consciousness followed a rather constant sequence from lethargy to noisy confusion,

and finally to coma. Thus, lethargy and drowsiness marked the onset in 13 patients, who slept most of the time and were disinclined to eat or talk, but were easily aroused and were oriented as to person, place and time. An adequate intake of food could usually be maintained in this phase only by tube or parenteral feeding. The rate of progression of the mental changes was variable, in fact, several patients passed through one or more periods of drowsiness and confusion before coma ensued.

Confusion, characteristically noisy, superseded the period of lethargy after a few days to several weeks, although in 5 patients preceding lethargy was not observed. In 8 patients the confusion was minimal, at times being manifested by a harmless wandering, particularly at night. Frank hallucinations were distinctly rare. Hypnotics were given to most of the patients who exhibited this disturbed state, and in 10 patients were followed by a deep sleep, which merged imperceptibly into coma. Paraldehyde was the most frequently used sedative, being given to 7 patients. The dose, administered orally or intramuscularly, varied from 6 to 68 cc given in from one to six doses. The largest individual dose was 14 cc, which was repeated in two hours. Of these 7 patients who received paraldehyde, 1 also received morphine sulfate and 1 a barbiturate. Because of severe abdominal pain, 1 patient received repeated doses of demerol, and 1, morphine sulfate. Another patient received repeated doses of paregoric because of persistent diarrhea.

Death occurred after twelve hours to six days of deep coma, although 14 patients died within the first two days. In our experience deep coma occurring spontaneously has invariably been fatal. The patients appeared as though they were merely sleeping, made no purposeful voluntary movements and responded less and less to painful stimuli. Thus, the comatose state was remarkable in the paucity of clinical signs other than the mental state, which almost alone distinguished it from the precoma period. The signs of liver disease remained essentially unchanged except for the appearance of clinical jaundice in 4 patients not previously jaundiced. Six patients were not jaundiced at death. The temperature, pulse and respiratory rate gradually rose during the coma, and in 5 patients the rise was associated with a terminal bronchopneumonia. Deep, regular respiration, particularly early in the coma, was one of the most characteristic observations. The blood pressure, usually normal or slightly low before the onset of coma, fell during coma and in 4 patients was below 90 systolic, 60 diastolic.

The pertinent laboratory data before and during coma are presented in Table 3. There was little change in the hemoglobin concentration (Sahli). The total white-cell count generally rose terminally so that it was below 5000 in only 2 cases, being

between 10,000 and 20,000 in 6 and greater than 20,000 in 3. In spite of presumably adequate fluid intake, oliguria was the rule during coma and was reflected by a moderate rise in the blood nonprotein nitrogen concentration in the 15 patients in whom the determination was made. The plasma carbon dioxide combining power was usually moderately reduced, although in 2 patients somewhat high values were found. In half the patients the blood sugar (Folin-Wu method) was determined, and in no case was a dangerously low value found. The

lowest being 68 mg per 100 cc. The abnormally high values in 3 cases were found after recent intravenous dextrose or tube feeding.

As measurements of liver function, the serum bilirubin,<sup>2</sup> thymol turbidity,<sup>3, 4</sup> cephalin cholesterol flocculation<sup>5\*</sup> and plasma prothrombin concentration<sup>6\*</sup> were determined. Although these studies usually revealed evidence of severe liver disease, there were no consistent or striking changes between those made before and during coma (Table 3). The urine urobilinogen was extremely variable although in a few cases the nonurobilinogen Ehrlich-reacting substances<sup>7</sup> were increased in the urine to exceptionally high values †.

The blood alpha amino nitrogen concentration<sup>8</sup> was determined in 5 cases during coma, and values varied from 3.6 to 4.9 mg per 100 cc of serum, all within the normal range. Amino acid tolerance tests in 4 of these patients were previously reported and showed only slightly higher blood concentrations of alpha amino nitrogen four hours after the infusion than those of normal subjects.<sup>9</sup>

Blood tyrosol (free phenol) values were determined by the method of Bernhart and Schneider,<sup>10</sup> as modified by Roen,<sup>11</sup> and were found to be either normal or somewhat elevated but did not differ significantly from values obtained in the same pa-

\*Determined at the Boston City Hospital Surgical Research Laboratory. Dr. Stephen J. Maddock, director.

†These urinary chromogens are poorly understood. The general term urobilinogen is used to designate them. Their chief constituent seems to be indol acetic acid.

tients before coma or in other patients with cirrhosis not in coma. This is in contrast to a small group of patients with uremia in whom the values were consistently elevated, as reported by others.<sup>12</sup>

The spinal fluid was characteristically clear, under normal pressure and without cells. Small amounts of bilirubin (0.1 to 0.4 mg per 100 cc) appeared in the spinal fluid occasionally, with extreme jaundice (bilirubin concentration of from 13 to 20 mg per 100 cc of serum).

Admission orders for all conscious patients included a high-protein, high-calorie diet, which was supplemented with brewer's yeast (40 gm per day), oral niacin (50 to 150 mg per day) and subcu-

an eggnog\* or a mixture of milk and a liver protein preparation†. They were well tolerated.

Parenteral dextrose in amounts from 1 to 3 liters daily and in concentrations of from 5 per cent to 20 per cent was administered to 14 of the 20 patients. Vitamins C, K and the B complex (thiamine, riboflavin, nicotinamide, pyridoxine and pantothenic acid), prepared for parenteral use, were usually added to the dextrose solution. The daily intake of these vitamins was usually very high, 1 or 2 ampoules‡ being used daily. In addition, each patient received from 50 to 150 mg of thiamine, subcutaneously, daily. Six of the patients were given 10 or 20 cc of unrefined liver extract daily in the

taneous thiamine (50 to 150 mg per day). However, most of these patients ate poorly, and only 3 of the entire group of 20 were thought to be consuming an adequate diet at the onset of the coma.

Therapeutic measures during coma were directed toward the prevention of infection, especially bronchopneumonia, and the maintenance of the patient's nutrition.<sup>13</sup> In an effort to control infection, chemotherapeutic agents were used liberally, penicillin being administered to 14 of the patients in this group.

An adequate intake of nutrients during coma was provided either by stomach tube or parenterally, or both. Although the possibility of inducing bleeding from esophageal varices by a stomach tube (Levin type) exists, we have never seen this complication. Tube-feeding formulas made use of either

intravenous infusion mixture. Two liver-extract preparations were used, one a standard preparation§ and the other¶ prepared specifically for intravenous use.<sup>15</sup> Both preparations were well tolerated, neither flushing nor pyrogenic reactions being observed with the method of administration used. In a few patients very large amounts (50 to 100 cc) of the latter preparation were administered. No

change in clinical condition that could be attributed to this form of therapy was observed

From 45 to 100 gm of one of two protein hydrolysate solutions\* were added to the intravenous infusions of 8 of the 20 patients. No pyrogenic reactions or apparently harmful effects were observed from the administration of these preparations in the presence of severe liver disease. In fact, as mentioned above, amino acid "load tests" have given no evidence of a significantly reduced tolerance in patients with severe liver disease as compared with that in normal persons.<sup>9</sup>

Central-nervous-system stimulants and analeptics were given to many of the patients. Caffeine,

Complicated Coma

Although the 20 patients in this group all died in coma and at autopsy had severe liver disease, they are considered as a separate group because each was complicated by another major pathologic state (Table 1). Seventeen patients had severe infection. Seven patients had pneumonia, 4 tuberculosis (in 3 of whom the disease was miliary), 4 peritonitis (in 3 secondary to the insertion of a peritoneal button<sup>18</sup>), and 2 bacterial endocarditis. Two patients lapsed into coma after bleeding from esophageal varices although there was no clinical evidence of shock. One patient had a hepatoma superimposed

benzedrine (amphetamine) sulfate and picrotoxin in moderate amounts subcutaneously or intravenously did not induce a response. In view of the reported effectiveness of sodium succinate in barbiturate narcosis<sup>16, 17</sup> 30 gm of this substance† was administered intravenously over a period of one hour to each of 2 patients. Marked flushing and tachypnea occurred, but no therapeutic effect was observed. Rapidly infused concentrated dextrose solution (usually 100 cc of a 50 per cent solution) failed to alter the state of coma in all but 1 patient. In this patient the coma became temporarily lighter but was then refractory to the further administration of dextrose.

on Laënnec's cirrhosis. The mental symptoms in this case may have been due to cerebral metastases. The historical data and physical findings concerning this group of patients are presented in Table 2. The lesser incidence of ascites, edema and collateral abdominal veins in the complicated group is evident.

The development of coma in these patients was an accelerated version of that seen in the uncomplicated group. In 8 patients the liver disease was far advanced and clinically indistinguishable from that encountered in the uncomplicated group. In the remaining 12 there was severe liver disease, but the complicating infection or hemorrhage was obviously the chief difficulty. It appeared as though the complicating factor had precipitated the terminal coma before it would have occurred in the natural course of the liver disease alone.

\*"Amgen" furnished by the Mead Johnson Company, Evansville, Indiana; "parenamine" furnished by Frederick Stearns and Company, Detroit, Michigan.  
† "Sodaxon," furnished by Brewer and Company, Incorporated, Worcester, Massachusetts.

The laboratory data were essentially the same as those in the uncomplicated group except for the presence of bacteremia in 6 cases. The white-cell count was not a reliable index of infection, being above 12,000 in only 6 patients and below 5000 in 5. Moreover, the white-cell count was frequently high in the uncomplicated cases.

Hypnotics and analgesics were administered to 8 patients in this group, and in some cases undoubtedly contributed to the development of coma. Paraldehyde was used in 7 patients in amounts of 6 to 96 cc over a period of a few hours to several days. Demerol was combined with paraldehyde in 1 case, as was morphine sulfate in another. One patient became comatose after 225 mg of demerol given in three doses over a period of twelve hours.

In addition to the therapeutic measures used for the patients with "uncomplicated" coma, vigorous treatment of the complicating factor was undertaken. Appropriate chemotherapeutic agents were administered. Sulfonamides (usually sulfadiazine) were not withheld because of liver disease if their use was indicated but were administered cautiously as recommended by Peterson, Deutsch and Finland.<sup>19</sup> Blood transfusions were used after acute blood loss from bleeding varices. That these therapeutic measures are occasionally effective is suggested by the fact that in the two years covered by this study, 4 patients with cirrhosis, not included in this study, recovered from coma. The coma in 2 was accompanied by severe infection and in 2 was associated with sedation.

### DISCUSSION

Since Frerichs's description, presented above, many attempts have been made to define both clinically and etiologically the coma in patients with liver disease. Leyden,<sup>20</sup> in 1866, noted a clinical resemblance of liver coma to kidney failure and suggested the term "cholemia," ascribing the coma to a retention of bile acids in the blood. This terminology has persisted, although the underlying concept has been generally discredited. Indeed, complete biliary obstruction is compatible with long periods of comparatively good health, and, in contrast, liver disease may terminate in coma with only minimal bile retention (Tables 2 and 3). Spence and Ogilvie,<sup>21</sup> in 1927, reported terminal "cholemia" in 21 cases of acute yellow atrophy of the liver, but were unable to elucidate the etiology on the basis of their clinical findings.

No specific clinical finding other than coma served to distinguish the comatose state in our patients. The patients appeared to be sleeping but could not be aroused. The presence of liver disease was usually obvious from the history and physical examination, although jaundice was not always present. Respirations were usually regular although commonly increased in depth and rate. Neurologic findings were likewise nonspecific.

The results of the usual laboratory tests were neither characteristic nor of help in elucidating the pathogenesis of the condition. Greene<sup>22</sup> similarly noted the lack of significant blood chemical changes. The terminal rise in blood nonprotein nitrogen observed could be correlated with oliguria, which was usually present in spite of an adequate fluid intake.<sup>22-26</sup> Our results do not indicate which fraction of the blood nonprotein nitrogen rises, except that it is not alpha amino nitrogen. Maddock<sup>17</sup> found a high undetermined fraction of blood nitrogen in hepatectomized monkeys. Croftan<sup>23</sup> suggested, in 1906, and others have subsequently concurred, that after liver damage the blood is flooded with "toxic" products of incomplete protein breakdown. The occurrence of mental symptoms and coma in Eck-fistula dogs fed high meat rations supports the toxin theory,<sup>29</sup> although others believe the cause in this instance to be an incidental infectious encephalitis.<sup>30</sup> The possibility that a toxic compound from altered protein breakdown, especially from the aromatic amino acids, might be found in the blood phenol fraction led us to measure the free phenol concentration. As with other blood constituents, any abnormality found (a rise in this case) was no greater in liver coma than in patients with severe liver disease not in coma. Thus, in spite of a long-continued search for a metabolic toxin in liver coma none has been demonstrated. In fact, Greene<sup>22</sup> has suggested that it is unnecessary to postulate a "toxin" to explain coma in disease of an organ with as profound biochemical importance as the liver.

Our patients failed to show significant hypoglycemia, however, most of them were given carbohydrate by mouth or glucose parenterally, both before and during coma. In only 1 case did the coma become significantly lighter in response to rapidly infused concentrated dextrose, and then the response was only transitory. Thus, the coma in these patients is not analogous to the hypoglycemic coma that develops in hepatectomized dogs and responds dramatically to the parenteral administration of glucose.<sup>29, 31</sup>

Recently, Snell and Butt<sup>32</sup> observed increased amounts of lactic and pyruvic acids in the blood of patients with liver coma and noted a clinical response to administration of parenteral glucose, niacin and thiamine. They postulated that coma in hepatic disease is due to an abnormality of carbohydrate metabolism related to deficiencies of these vitamins. Patek<sup>33</sup> has confirmed the beneficial effect of the administration of glucose and vitamins. Simple vitamin deficiencies did not appear to be responsible for the coma in our patients since large supplements were given to all, both before and during coma. However, the observation of Williams and Bissell<sup>34</sup> that in patients with liver disease the formation of cocarboxylase from thiamine is impaired indicates a metabolic abnormality in these pa-

tients that may explain the high blood pyruvate found by Snell and Butt<sup>32</sup>. It seems likely that this and other biochemical abnormalities exist in patients with liver disease and may play an important role in the genesis of coma.

Although the metabolic defects responsible for coma in liver disease have not been explored, the etiologic importance of infection, hemorrhage and sedatives is clear, the first two at least, may be amenable to specific treatment.

Infection was the single most common known factor in the precipitation of coma in our series, being considered of major importance in 17 patients. The coma so produced was indistinguishable from that developing spontaneously. The exact nature of the influence of infection upon the metabolic processes of the liver is not known. Fever itself may cause hepatic necrosis, which is evidenced clinically by jaundice and bromsulfalein retention<sup>33, 36</sup>. Furthermore, jaundice occurs in a small percentage of patients with pneumococcal pneumonia, especially in pneumonia complicated by septicemia, and is thought to be due, at least in part, to liver damage<sup>37</sup>. Beeson et al<sup>35</sup> have demonstrated that the hepatic-vein blood in cases of endocarditis contains strikingly fewer bacteria than either peripheral venous or arterial blood, suggesting that the liver is a major site of removal of circulating bacteria. The possibility of concentration of bacterial toxins in the liver thus exists. The pneumococcus, tubercle bacillus, and gram-negative organisms from the gastrointestinal tract were the bacterial agents responsible for the infections encountered in our patients, however, little is known of the effect upon the liver of the toxins elaborated by these organisms.

In patients with "medical shock" due to severe infections, indications of damage to the liver have been observed both clinically and pathologically<sup>39</sup>. The profound circulatory changes that occur with infections and fever<sup>40</sup> may diminish the oxygen supply to the liver and may thus be comparable to the situation following hemorrhage, as pointed out below.

Acute hemorrhage from ruptured esophageal varices precipitated coma in 2 of our patients. Recent studies on the effect of acute blood loss have shown a greater reduction in portal blood flow than is suggested by changes in the systemic blood pressures, and further that the oxygen content of the portal blood is also markedly decreased<sup>41-44</sup>. Since the liver receives from 75 to 80 per cent of its oxygen from the portal system, marked hepatic anoxia might be expected from severe hemorrhage, and, according to the observations of LePage,<sup>45</sup> depletion of adenosine di-phosphate and triphosphate would occur.

In addition to infection and hemorrhage, the injudicious use of sedatives was a factor in the production of coma in our patients. In some cases it

was clearly the major factor, whereas in others it appeared only to be contributory, being given during the phase of excitement and serving to hasten the appearance of coma. Most forms of sedatives seem to be poorly tolerated by patients with liver disease. This is especially true of morphine and other alkaloids<sup>46</sup>. Fagin and Thompson<sup>47</sup> observed that of 15 patients dying in liver coma, the coma in 6 followed the administration of morphine by a few hours. In fact, as little as 10 mg of morphine sulfate may induce coma lasting up to three days or until death supervenes. There is little or no evidence that small doses of morphine actually damage the liver, but it is probable that with liver disease the body is less able to get rid of the drug, since a portion of administered morphine is conjugated in the liver with glucuronic acid<sup>48-50</sup>. After experimental liver damage the excretion of free morphine is increased and that of the glucuronide decreased<sup>51, 52</sup>.

Many of the barbiturates are likewise poorly tolerated in patients with liver disease<sup>53</sup>. Like morphine, most are in part, if not largely destroyed, conjugated or excreted by the liver (especially amytal, pentobarbital, seconal and evipal).<sup>54-56</sup> Barbitol and phenobarbital are to a greater extent eliminated by the kidney but, although probably safer than the others, are not without danger. Paraldehyde has been a favorite hypnotic for use in alcoholism and, because of the frequent concurrence of the two conditions, has often been used in patients with liver disease. In our experience, however, it may be highly dangerous. Levine<sup>57</sup> has shown in animals that the drug is metabolized largely by the liver and that it persists in the blood of both men and animals for long periods when liver damage is present. The problem of providing adequate sedation or analgesia in patients with severe liver disease is, indeed, a difficult one, and at present there does not appear to be a satisfactory solution. Although the danger of sedatives in liver disease must not be overlooked, it should be pointed out that patients to whom sedatives have not been administered also develop coma.

#### SUMMARY

The clinical and laboratory studies on 40 patients with severe primary liver disease who died in coma are presented. Liver coma is a distinct clinical syndrome characterized by a progression from lethargy to noisy confusion, to coma and usually to death. The syndrome occurs in patients with severe liver disease, either spontaneously or as the result of infection, hemorrhage or sedation. In half the patients, the coma was precipitated by infection (17 patients), acute hemorrhage (2 patients) or cerebral metastases (1 patient). Central-nervous-system depressants have a prolonged action in patients with liver disease and in this way are believed to play an important role in the genesis

of liver coma. Aside from evidence of severe liver disease, the physical examination and laboratory findings during coma are not distinctive nor are they significantly different from precoma findings. Treatment, which is generally unsatisfactory, is directed at maintenance of nutrition, control of infection or hemorrhage and avoidance of sedatives. Analeptics, including glucose, sodium succinate, caffeine, and benzedrine, are without effect upon the comatose state.

## THE USE OF BRILLIANT GREEN IN THE TREATMENT OF CHRONIC ULCERS OF THE SKIN

ARTHUR W FEINBERG M D \*

GREAT NECK, NEW YORK

THE multiplicity of treatments reported in the literature on the subject of chronic ulcers of the skin is evidence that no one treatment has adequately met the required standards of being bactericidal, nontoxic, stimulating to the growth of epithelium and granulation tissue, giving prompt, effective and uniform results and being cheap and easy to use. During a tour of duty with the Army in the Pacific Theater of Operations, I had occasion to see a number of cases of chronic skin ulcerations, of varied etiologies. Each of these cases was treated with the rosaniline dye, brilliant green, and the results obtained indicate that this drug is the one that most nearly meets the stated requirements.

Chemically, brilliant green, like gentian violet, crystal violet and methyl violet, is a derivative of triphenylmethane. These rosaniline dyes are inhibitory to the gram-positive micro-organisms, particularly staphylococci, *Corynebacterium diphtheriae* and *Pseudomonas aeruginosa*. Brilliant green, though employed sporadically for many years because of its sterilizing properties, is not an official drug as yet. It has received trials in the treatment of erysipelas and leprosy, and, in recent years, Aldrich<sup>1</sup> has combined it with gentian violet and acriviolet in his triple-dye treatment of burns. The dye has been used most frequently in bacteriologic staining and can be obtained in the form of a green powder, which is readily soluble in water and alcohol.<sup>2,3</sup> Narat,<sup>2,3</sup> who has written extensively about brilliant green, claims that the aqueous solution is not stable, but in my experience this is not true, inasmuch as stock aqueous solutions continued to give excellent clinical results months after their preparation.

Brilliant green was used in over 20 cases of chronic ulceration of the skin. It is realized that this series is too small to justify extensive conclusions, but the results were so uniform and so excellent in all cases that it was decided to present them in the form of a preliminary report in the hope of stimulating further investigations regarding its use. In all cases the dye was used as a 2 per cent solution in distilled water. After thorough cleansing of the ulcer with hydrogen peroxide and alcohol, the dye was painted on daily until healing was progressing well — generally about seven to ten days. It was then applied every other day until healing was complete. The ulcer was covered with a dry sterile dressing after each treatment. The patient was advised to rest as much as

possible and to sleep with the affected extremity elevated. Otherwise no instructions or treatments were given.

### CASE REPORTS

CASE 1 M J R., a 25-year-old Filipino merchant seaman, was first seen in November, 1947, complaining of a large, rapidly progressing ulcer on the dorsum of the right foot (Fig 1). About 1 month prior to his first visit his foot had

FIGURE 1 A Chronic Ulcer of One Month's Duration before Treatment

been bruised by a steel cable, and the resulting small wound became infected and quickly broke down. Upon examination the ulcer measured 3.8 by 5.3 cm, the base was deep and was covered with dirty, evil-smelling necrotic tissue. No evidence of healing was seen. Pain was moderate. The patient was

FIGURE 2 Ulcer after Five Applications of Brilliant Green

placed on hot soaks, bed rest and elevation of the leg for a 2-day period, with no change in the appearance of the lesion except that the size of the wound had increased slightly. Brilliant green was applied. After one treatment with the dye, the necrotic exudate had lessened considerably, the odor had practically disappeared, and evidences of healing were already present. The pain and discomfort in the wound were completely gone. After only five applications of the dye, the necrotic exudate had disappeared, the base of the wound was level with the surrounding skin and was composed of clean

\*Intern in medicine, Maimonides Hospital (Israel Zion Division) Brooklyn, New York.

†Manufactured by National Aniline Division, Allied Chemical and Dye Corporation, New York City.

healthy granulation tissue, and epithelium was growing rapidly at the edges. The wound now measured 3.3 by 2.6 cm, having closed 5 to 7 mm in less than 1 week (Fig. 2). Healing progressed rapidly and steadily so that on the 26th day of treatment, after eighteen applications of brilliant green, heal-

FIGURE 3 Ulcer Completely Healed on the Twenty-Sixth Day of Therapy, after Eighteen Applications of the Dye

ing was complete and the skin surface intact (Fig. 3). Follow-up examination 1 month later showed no evidence of recurrence.

CASE 2 L. R., a 10-year-old Filipina, first appeared early in December, 1947, with a large, deeply excavated tropical ulcer over the medial malleolus of the left leg (Fig. 4). It had started 3 months before as a slight scratch, which had become infected and had grown progressively larger and deeper. She had received intensive treatment with hydrogen peroxide soaks, sulfanilamide crystals and locally applied neosarsphenamine before coming to the clinic, without retarding the progress of the lesion. Upon examination, the

FIGURE 4 A Tropical Ulcer of Three Months' Duration before Treatment

wound measured 3.4 by 3.0 cm, and the edges were markedly indurated. The base was 4 mm below the skin surface and was covered with the same type of slimy, malodorous, necrotic discharge as that in Case 1. Pain was marked, especially at night. After one application of the dye, the pain was gone, the swelling and induration about the ulcer had lessened, the base of the wound was starting to fill in, and the exudate, though still profuse, was no longer foul smelling. After eleven applications of brilliant green, the surface of the ulcer was completely level with healthy granulations, and epithelization was progressing rapidly. The ulcer now measured 1.5 by 1.8 cm, a closure of more than 70 per cent of the surface area. There was no exudate (Fig. 5). Healing continued to be rapid, and after 29 days of treatment, which comprised 17 applications of the dye, the patient was discharged with the ulcer healed (Fig. 6). Six weeks later, she returned for a follow-up visit. The ankle looked perfectly normal, and there was no evidence of regression (Fig. 7).

CASE 3 C. D., a 53-year-old man employed as a merchant seaman, appeared in the clinic in August, 1947, for the first time, complaining of an infected ulcer over the anterior surface of the left tibia of 1 week's duration. The patient gave a

FIGURE 5 Progress of Healing after Eleven Applications of Brilliant Green

history of mild diabetes mellitus, which was kept under control by dietary measures. His cardiovascular history was completely negative. He had struck his shin 1 week before, received an abrasion that refused to heal, rapidly became infected and then ulcerated. Physical examination revealed

FIGURE 6 Healing of the Ulcer on the Twenty-Ninth Day of Therapy, after Seventeen Treatments with the Dye

the heart to be normal, and there was no glycosuria on repeated examinations. On his left leg he had a circular wound, 2.5 cm in diameter, covered with a scab. Removal of the scab exposed a shallow, dirty, infected ulcer showing no signs of healing. Both legs were covered with numerous scars, the

FIGURE 7 Follow-up Photograph, Six Weeks after Completion of Treatment, Showing a Normal Ankle

results of previous leg ulcers similar to the present complaint. None of these had healed in less than 3 months' time. The patient was treated with hot soaks, thorough daily cleansing, zinc oxide ointment and sterile dressings for 1 week. At the end of this period, the infection had subsided somewhat, but

the size of the wound was unchanged and no healing tendency was noted. Brilliant green applications were then started, and other treatments suspended. Improvement was noted almost immediately and the ulcer was completely healed 16 days later, after fourteen applications of the dye.

CASE 4 S L, a 32-year-old Filipino man employed as a clerk, was first seen in September, 1947. Almost 4 months before, he had developed a carbuncle on the left side of his abdomen. He received no medical attention, and the carbuncle gradually emptied of itself. One month after onset, it had become an indolent, nonhealing ulcer. On first examination, the ulcer measured 2.5 by 2.4 cm and was moderately infected. It was shallow, but the base showed no clean granulations. Brilliant green applications were started at once, and 1 day later, evidences of healing could be noted. In 11 days after only seven dye applications, the ulcer was completely healed, and the patient discharged. Follow-up examination 2 months later showed no recurrence.

### DISCUSSION

Brilliant green, a rosaniline dye of the triphenylmethane series, seems to offer many advantages in the treatment of chronic, indolent ulcers of the skin. It is bactericidal for many of the common pathogenic bacteria, has a high stimulating effect on the growth of epithelium and granulation tissues and counteracts the malodorous discharge common to this type of case. It is completely nontoxic, does not

irritate tissues and has the added advantage of being low in cost. It can be as easily used in the doctor's office or the patient's home as in the hospital clinic. The staining of normal skin that occurs incident to its use can be removed readily by washing with alcohol.

### SUMMARY

Experiences in a limited series of cases of chronic skin ulcers with a 2 per cent aqueous solution of the rosaniline dye, brilliant green are presented.

The advantages of brilliant green — its bactericidal action, its stimulative effect on epithelium and granulation tissue, its nontoxicity, cheap cost and ease of application — are cited.

It is believed that the use of brilliant green merits further trials in the treatment of all types of chronic ulcers of the skin.

## THE RELATION BETWEEN THE INDUSTRIAL PHYSICIAN AND THE FAMILY DOCTOR\*

THOMAS L. SHIPMAN, M.D.

WEST LYNN, MASSACHUSETTS

DURING the decade from 1911 to 1920 all but a handful of states enacted workmen's compensation acts and thereby brought into being that peculiarly hybrid creature, the industrial physician. Back in those early days the propriety of entering such a low-born specialty was questionable, and there can be no doubt that a number of poorly qualified doctors entered this field. There were in addition, however, men of unquestioned ability and integrity, and as pioneers in a new and uncharted field they endured the scorn and insults of other doctors, and at the same time they evolved the fundamental knowledge and procedures that now form the basis of industrial medicine, a specialty today in its own right. In general the relations between the industrial physician and the general practitioner are now harmonious, but there is still room for improvement, and there are probably justifiable complaints on both sides.

I should like to pause here for a moment to define roughly my own ideas of what constitutes an industrial physician and his job. An industrial physician should in the first place be a well trained, capable and honest doctor. As Professor Philip Drinker has

often expressed it, a doctor is not good enough to care for the employees of a plant unless he is also good enough to care for the boss and the boss's family. The industrial physician must in addition have an interest in the employees in health as well as in sickness. Far too common is the self-styled industrial doctor who is nothing but a "patcher-upper", this man usually knows nothing about the workings of the plant, the materials employed, the procedures carried out or the nature of the actual jobs performed by the workers. How can a doctor carry out a routine pre-employment physical examination if he doesn't know intimately the demands and requirements of the job in question? In the year or so following the war I had the opportunity of talking with a large number of young doctors just out of the service who were looking for industrial jobs. Actually all but a tiny minority were looking only for a sort of insurance job, bits of traumatic surgery with fees guaranteed. They had not the slightest interest in supervising the well-being of the healthy worker and in trying to keep him that way.

Last year at the Atlantic City meeting of the American Medical Association Dr. Poole,† of the Lockheed Aircraft Corporation gave a paper on this

\*Presented at the annual meeting of the Massachusetts Medical Society on May 25, 1949.

†Instructor in industrial hygiene, Harvard School of Public Health; assistant in medicine, Massachusetts General Hospital; consultant in industrial medicine, Salem Hospital; works physician, Lynn plants of General Electric Company.

†Poole E. E. General practitioner as adjunct to industrial surgeon. *Occup Med* 4 293-304 1947.

same general subject. Without any question he stole much of my thunder, but running in second position I have the opportunity of re-emphasizing many of his points. In one particular I shall undertake to split a hair. Dr. Poole chose as his title, "The General Practitioner as an Adjunct to the Industrial Surgeon." I should prefer to put the shoe on the other foot and state that the industrial physician—or surgeon—is more properly an adjunct to the general practitioner. Regardless of who gets top billing, the aim of both is exactly the same, and they must be regarded as collaborators. Let us briefly consider this point. The family doctor, or any physician in private practice for that matter, ordinarily sees his patients only when they are sick or ailing. When he does see them his natural desire, unless he is a charlatan, is to restore them to health as quickly as possible. In other words, he wants to get the patient back to a normal productive life as soon as it is safe and proper. This is naturally of particular importance if the patient is the wage-earner for a family. The industrial physician has exactly the same idea, he is perhaps more concerned with keeping the well person healthy and in protecting the handicapped person from further damage. His purpose, his *raison d'être*, therefore, is to keep the human element in industry efficient and productive. Naturally this is advantageous to the industry and its management, but it is even more of a boon to the individual.

Only 10 per cent of the total time lost in industry because of sickness is the result of occupational disease or industrial injury. The industrial physician who interests himself solely in the care of injuries is no more than nibbling at the corner of the problem. He is obligated to consider all phases of the employees' make-up just as much as the family doctor must give thought to the occupational aspects of his patients' histories. Your work and mine, therefore, overlap, and where they do not overlap, they supplement one another. Let us consider a few specific situations in which general medicine and industrial medicine do overlap and in which apparent differences of opinion arise.

First of all there is the problem of the preplacement physical examination. This is one of the first contacts that a new worker makes with his future employer. The examining physician assumes that the man is healthy—at least he walked in under his own steam ready to go to work. Unlike the hospital physical examination, abnormal findings here come usually as a surprise. The preplacement examination is brief but more searching than one might think. The findings are considered not as pathologic entities but as they relate to the specific job the man is to do, the requirements for a draftsman and an outdoor laborer obviously are not the same. Occasionally it will become apparent that a man's physical condition and his job do not go together, and the doctor has to say, "No, it would be a serious mistake

to permit this man to do this type of work—he might be able to do some other job, but he can't do this one." In many cases the man himself is unaware of the significance of his disability, and he feels hurt, not to say insulted.

Nobody wins if a man is permitted to go to work on a job for which he is unsuited, it is the responsibility of the examining physician to keep the square pegs out of the round holes. Frequently, a disappointed worker goes straight to his family doctor, and that is just where he should go, more often than not it has been suggested by the examining doctor that he make the visit. You would be astonished at the number of perfectly reputable physicians who disregard entirely the warnings of the plant physician and argue heatedly that the man is able to go to work, even though they have little or no idea of the precise nature of the work and its demands.

Physicians doing a good deal of examining for large industries become fairly proficient in discovering the elusive hernia. One would think that most doctors would be somewhat guarded in flatly contradicting the statement of an experienced examiner that a definite hernia has been found, and yet that is done repeatedly. It might be mentioned that the outpatient departments of the large hospitals, where the examinations are performed by relatively inexperienced house officers, are particularly frequent offenders in this regard. I am frank to admit that at no time in my hospital experience have I ever learned how to find hernia except one visible at ten paces.

The pre-employment—or preplacement—examination is an ideal opportunity to discover pathology in its earliest stages. I can think of no more common-sense form of preventive medicine, and I have enough faith in the profession to believe that every doctor would prefer to have one of his own patients come to him with a condition easily correctible rather than something neglected and beyond repair. Sometimes one wonders even about that, we recently sent a man back to his family doctor after a chest x-ray film had revealed a suspicious apical shadow. This doctor was utterly scornful and said that the patient could not have tuberculosis, since he had neither cough nor loss of weight.

Local practitioners are frequently critical in claiming that industrial clinics offer treatment for non-industrial conditions. In my own clinic approximately 20 per cent of our total visits are listed as being for nonindustrial complaints, and this seems to bear out the criticism. However, most of these visits are for heartburn, runny noses, headaches, hangovers, nosebleeds, diarrhea and similar trivialities. These are not problems that send a person to his family doctor—they are the conditions that send the child to and are treated by its mother (not the hangovers, perhaps). If we should deny attention to these people they would not go to their doctors—they would go if anywhere to the corner drugstore. I contend that it is distinctly within the

province of the industrial physician to see and treat these minor problems if they are of such nature that the patient can be given relief and returned to finish his day's work in safety. It is also this doctor's responsibility to make as certain as possible that the bellyache is not appendicitis, that the headache is not a brain tumor and that the diarrhea is not a cancer of the rectum. All the patients whose problems seem to demand a bit more than simple first aid are automatically referred to their family doctors for further consideration. The old complaint that the industrial doctor is stealing the bread from the mouth of the family doctor is definitely not justified.

Acutely sick patients, of course, are seen in every industrial clinic. Coronary-artery attacks, renal colic, appendicitis and bleeding or perforated peptic ulcer turn up in industrial practice not infrequently, and the disposition of the case is usually decided on after a telephone conversation with the family doctor. The early observations made in the case, together with simple laboratory work, will usually be of material assistance in making the diagnosis promptly and in saving the patient much time and discomfort. The industrial doctor does not want to take care of these patients, however, he wants to get rid of them, to see them placed in proper hands just as soon as possible.

In addition to the acutely sick persons many men with serious but noncritical conditions come to the industrial clinic. This group includes patients with diabetes, cardiac disease, ulcers, asthma, varicose veins, hemorrhoids, arthritis and a host of other conditions. Some of these men realize that all is not well with them and come to the company doctor seeking advice. They want to know where to go for proper treatment, or for relief. They may be sent to the dispensary by their foremen, who have noticed some indication of failing health, they may even come at the suggestion of the family doctor. Such situations call for a certain amount of diagnostic procedure before one can intelligently advise a man regarding the course to follow. It is important to know whether the problem is serious or trivial, and whether it needs prompt attention or elective treatment. Every large industrial clinic today has x-ray facilities, an electrocardiograph and a laboratory. The use of these diagnostic aids in industry is no attempt to supplant similar facilities elsewhere; it is simply to provide a preliminary survey that, it is hoped, will be of value and help in the ultimate solution of the patient's problem. The thoughtful wharf owner does not object to the placing of channel buoys to guide ships into the harbor.

There is, I should point out, an increasing willingness on the part of large industries to provide this preliminary diagnostic service for more and more people. Periodic physical examinations are required for certain workers in hazardous trades, and the same service is being offered on a voluntary

basis to larger and larger groups. In every case the information is available for the family doctor, and frequently it is sent to him whether he wants it or not.

A man came to my office some time ago complaining of a lump in his groin. He was a laborer, foreign-born, and spoke English only with difficulty. Instead of a lump in one groin he had lumps in both—large, egg-sized lymph nodes. The axillary lymph nodes were also involved. He was referred to his family doctor and returned a day or so later with a note from the doctor stating that he was suffering from chronic bronchitis and was able to do his work. I sent him back a second time with firmer instructions. A second note from the doctor admitted the presence of an enlarged inguinal lymph node on one side, and suggested that the man be changed to another job. This time I took no chances and wrote to the doctor urging biopsy and appropriate treatment. My letter was ignored and so was the patient's disease. Some time later the man reappeared with a letter from another doctor. This stated that the man had a generalized rash, occupational in nature, and that he should have a different job. It also stated that night-shift work seemed to be bad for the man. By this time there was massive enlargement of the inguinal, axillary and subclavicular lymph nodes, easily visible from a considerable distance. It might be said that I forced the issue this time, and the patient has received adequate treatment for Hodgkin's disease.

Another man, a leading engineer, came in for a routine physical examination. Both of two urine specimens showed large amounts of sugar. At my suggestion he went to a doctor of his own choice, an eminent internist in this city. Here he was given a clean bill of health and told not to worry. A year later he returned to me saying that he had lost 25 pounds and that he seemed to have developed an uncontrollable thirst. He is now taking insulin. Here I think that both doctors were at fault,—I for feeling that a physician of his eminence could not make a mistake, and he for feeling that anything coming out of an industrial clinic was probably unreliable.

In no situation is the need for co-operation greater than in that of the man returning to work after an illness. Almost every industry, certainly all the large ones, have certain rules and regulations concerning time away from work because of illness. It is common practice for industry to request from the attending physician a note stating that the patient is in his opinion ready to return to his job, and this also provides an opportunity to suggest any limitations or suggestions about the man's work that might be necessary. You would be amazed at the number of notes of this sort which are absolutely insincere and dishonest. No, I am not the only one who has been disgusted with this

situation Let me quote from Dr Poole's paper, which touches on the same problem in California

These letters are commonly referred to by personnel men and foremen as "S2 letters" I frequently hear scornful remarks from plant supervisors who believe that the ethics of the profession can be winked at for small fees and that a physician can be induced to write anything I must confess that after reading thousands of these letters I have many times shared their opinions

It is a sordid bit of business and I doubt if even the so-called patient can have much respect for the doctor who would stoop so low The industrial physician or personnel director must be pardoned, I think, if he refuses to accept as gospel a note that says that a patient has been ill and under a doctor's care, unable to work for two or four or six months because of hypotension or secondary anemia, nervousness or general debility The pattern is unmistakable, and the authors only too well known

There is a brighter side to this problem, however, and nothing gives a plant doctor more pleasure than to work together with the family physician in arranging suitable hours and conditions of work for the patient who is recuperating from severe illness Many physicians fail to remember what a bad enemy the clock is to the patient who is scarcely out of his convalescent stage Just sitting at a desk until the clock points to five is fatiguing to the person who is "out of training" Not infrequently the industrial doctor must apply the brakes in such a situation, sometimes even insisting that the patient remain away from work entirely for a week or so longer than his own doctor has advised

Quite a different situation arises when a doctor in all good faith requests that one of his patients be granted a leave of absence from work, or be given a different job, or be changed to a different shift Frequently the necessity for the recommendation is obvious, and appropriate action will be taken *if this is possible* Please note those words, "if this is possible" Sometimes it is not possible to carry out the proposed measures Every industry has definite rules and regulations regarding leaves of absence, for example, and these must be adhered to if the rights of all are to be protected In addition, nearly every industry has a complicated system of rules regarding job seniority, these rules are usually not of industry's seeking or choice, but they must be followed Ordinarily it is not possible, for example, to have a short-service man on a night shift displace a longer service employee on the day shift, even though the former's peptic ulcer makes it impossible or inadvisable to continue to work at night Here is a perfect stalemate, and the poor family doctor doubtless feels that the industry or its doctor is failing to co-operate in the care of the patient Actually the desire to co-operate is there but successfully blocked by conditions quite beyond the doctor's control

So far I have talked very glibly about industrial medicine as though all workers had available the same highly organized medical departments as those existing in the large corporations We all know that this is not so Actually, many of the workers in Massachusetts have available little or nothing in the way of competent medical supervision There is no industry so small that it should not and cannot have this medical supervision, but only a handful seem to recognize the fact The management of a small plant usually believes that it has done everything necessary if it has a nurse and a first-aid room, forgetting that this nurse needs a doctor's supervision No nurse should be asked or expected to work unless her duties and procedures are outlined and followed by a physician Simply having a doctor on call for emergencies does not constitute adequate supervision

This, however, is a situation that cannot be corrected overnight If a real problem exists and the family doctor wishes to make specific recommendations about a man's work, there are certain procedures that may be employed First of all, let me join with Dr Poole in condemning the note that starts off, "To whom it may concern" If no medical supervision for the patient exists at his place of work, one should find out the name of the ultimate boss, the manager, the president or owner, who should be addressed directly either by sealed letter or by telephone If the patient is entrusted with the note he should be told to see that it gets to the person to whom it is addressed and not to anyone else It may take an extra day to have the patient find the name of the proper person, but this delay is justified A letter sent by mail or a telephone call will permit far greater frankness and emphasis than is ever possible in an open note that is handed to the patient

The average doctor when taking his patient's present and past history usually exhibits a reasonable and healthy skepticism In considering an occupational history his attitude can only be described as gullible If a patient says that his job is dusty the doctor more often than not screams "silicosis" before he considers either the patient's symptoms or the nature of the dust He criticizes a job on the grounds of overfatigue and advises a leave of absence without considering the fact that the man is spending his leisure time building a house or tending a bar He deplores the heavy work a man does without finding out what that work consists of An unbelievable number of cases of scabies have been diagnosed as occupational dermatitis, and there appears to be a total inability in the medical profession to discriminate between a toxic hazard and a bad smell Let me assure you that industry welcomes inquiries on these subjects It is a pity that it is not more practical for doctors

actually to visit the places where their patients work, to see for themselves what the conditions are, and to find out what the working environment is

Every patient is affected either directly or indirectly by jobs and wages. Sitting at a desk in a bank is a job just as surely as standing at a lathe or a boring mill. The effect of poor adjustment to a job may be even more damaging to a wife or child than to the worker in question. You, therefore, have a stake in industrial medicine whether you want it or not. Where industrial medicine is practiced well it deserves your support. Where it is practiced poorly and improperly it deserves your constructive criticism more than your condemnation. Where medical supervision of workers is non-

existent your scorn of management that is unwilling to provide it should be followed by your help in showing how it can be obtained. The working man spends forty or more of the one hundred and sixty-eight hours in a week at his job. You cannot disregard this period, and your patient cannot afford to have you do so. Where good industrial medicine exists, cultivate it, get in the habit of using it, learn the ways in which it can help you to get your patients well and keep them that way. Accept the challenge of the missionary work needed to improve industrial medicine and extend its benefits to an ever-increasing number of working men and women, who, incidentally, are your own patients.

## FENESTRATION SURGERY FOR DEAFNESS

### Present Status

CHARLES I. JOHNSON, M.D.\*

BOSTON

THE general practitioner is being increasingly plagued by newspaper and magazine publicity describing new technics in medical and surgical therapy. Too often he finds himself confronted with the unpleasant chore of blasting the hopes falsely raised by some garbled or, at best, premature report of a "cure" for high blood pressure, arthritis, asthma, sinusitis, deafness and so forth. The situation takes on the proportions of a real problem, moreover, when the doctor must decide what answer to give a patient who asks about a technic that has really proved to be effective but only under certain conditions and for certain types of sufferers.

A particularly good example of a therapeutic technic that can tremendously improve a bodily defect and, at the same time, remove its ill effects on the personality is the novovalis fenestration operation. There has been a good deal of publicity about this operation in the decade since Lempert developed the one-stage technic for the cure of deafness due to otosclerosis, and more and more patients are coming to their physicians for information and advice about their chances of benefiting from it.

The first point the physician must determine in deciding whether the patient should consult a surgeon skilled in this technic is the cause of deafness in the particular case with which he is dealing. The fenestration operation is successful only for deafness of otosclerotic origin. Otosclerosis is a histologic lesion in the bone of the inner ear and

takes the form of circumscribed, sharply defined inlaid areas of new bone formation of unknown etiology and microscopically somewhat like Paget's disease or osteitis fibrosa. In otosclerosis the piling up of new bone formation is usually about the foot plate of the stapes, and the deafness progresses as the fixation of the stapes increases. The fenestration technic consists in making a new fenestra in the inner ear so that sound waves can by-pass the obstructed middle-ear circuit.

The general practitioner can make at least a tentative diagnosis of otosclerosis on the basis of history and symptomatology. The patient usually gives a history of bilateral deafness beginning in adolescence or early adult life and, as a rule, becoming progressively worse. Although in some cases deafness does not develop beyond the point where practical hearing is possible, most patients suffer progressive impairment to a degree where hearing loss is incapacitating. Many of them ultimately show nerve degeneration. There may be found a past history of acute otitis media, but this finding does not preclude a window operation if the eardrum membrane is intact. A chronic sup-purulation of the middle ear on the other hand, is a contraindication.

As part of his general information about this disease, the physician may find it helpful to know that a hereditary factor has been found in 53 per cent of cases. Also, about six times as many women as men have otosclerosis, and in about half the female patients impairment of hearing increases during pregnancy.

\*Fellow to the Winthrop Foundation, surgeon, Massachusetts Eye and Ear Infirmary, Massachusetts General Hospital, assistant surgeon, Children's Hospital, chief of otolaryngology, Faulkner Hospital.

It is characteristic of the otosclerotic patient to hear well over the telephone and in noisy places such as a subway or railroad train. Good hearing over the telephone, it is true, may be found in chronic catarrhal or chronic adhesive deafness, but here one can elicit a history of nasal allergy or chronic upper respiratory infections and ear-aches with or without discharge. Examination provides another differentiating point in otosclerosis: the eardrum is normal, without perforation or discharge, and gray or pink in color unless complicated by an isolated attack of otitis media. In the other type of deafness mentioned, the eardrum may be thickened, atrophic, scarred and possibly perforated anteriorly.

Tuning-fork tests will show the otosclerotic patient to have prolonged bone conduction and diminished air conduction. He characteristically hears well with a hearing aid of either the air-conduction or bone-conduction type. In fact, this type of patient does not have to rely solely on the fenestration operation for help, even if he proves eligible for it by all the various criteria used by the surgeon in advising operation: he can always fall back on a hearing aid instead of submitting to surgery. The decision about undergoing surgery actually rests with him, but many of these patients are not willing to use a mechanical device despite its effectiveness.

Certain other factors must be taken into consideration in judging a patient's chances of benefiting from a fenestration operation. One of them is age. Persons between eighteen and fifty are the most eligible, although younger and older patients have been operated upon with good results. Another factor is emotional stability. Since not every operation can be guaranteed to be an unqualified success, and the aftertreatment, in every case, is necessary and since a few patients occasionally develop post-operative vertigo, the emotionally unstable person is a poor psychologic risk.

When a patient is referred to an otologist for study preliminary to possible fenestration surgery, a number of devices designed to gauge cochlear-nerve function help the surgeon make his decision. He will use air and bone audiograms, tuning-fork tests, the speaking tube and word tests played on a recording machine.

Although the fenestration does not give perfect hearing, it does make possible practical hearing that enables the patient to carry on a conversation, attend lectures or church and otherwise live a normal life. For properly selected patients, the chance of bringing the hearing to a permanently serviceable level is about 50 per cent. By permanent is meant a period longer than two years, after which period no patients with successful cases have lost their hearing. I performed my permanently successful cases of oldest standing in December, 1941, and these patients have lost none of their hearing gains. Of 64 operations performed between December, 1941, and April, 1946, 31 were successful — or 48.5 per cent.

Patients who have undergone successful operations say that their hearing has none of the distortion produced by the hearing aids they formerly had recourse to and also that they can be more selective in their hearing. In other words, the hearing made possible by the fenestration operation is more satisfactory than that effected by a hearing aid because it is more natural.

What to me is the most striking effect produced by a successful fenestration operation is the extraordinary change for the better in the patient's personality. The self-conscious, dejected, hypersensitive person with inferiority feelings living a life circumscribed by the limitations put on his activities by deafness emerges from this operation a more self-confident, happy and better adjusted man or woman possessed of an energy, enthusiasm and joy in living that is tremendously rewarding to see.

## MEDICAL PROGRESS

### RENAL DISEASE\*

ALASTAIR D HALL M D,† AND JOHN A LUETSCHER, JR, M D‡

MONTREAL, CANADA, AND SAN FRANCISCO, CALIFORNIA

WE ASK the reader's indulgence for some liberties in the selection and presentation of recent developments in renal disease. The literature on the kidney is too large to permit any complete description in these few pages. We have therefore chosen a few subjects of current interest for discussion. These include some studies of the earlier stages of glomerular nephritis and a glimpse of the gradually evolving cardiovascular-renal relations. The curious effects of large doses of vitamin D on the kidney are mentioned. The acute renal tubular injury that accompanies many types of bodily injury is now recognized as one of the commonest and most important forms of renal disease. Its etiology is discussed and related to the novel studies of Trueta on the renal circulation. Finally, some new methods for the treatment of acute renal insufficiency are described.

#### GLOMERULAR NEPHRITIS

Two important new books on nephritis have appeared this year. In his scholarly work on Bright's disease, Christian<sup>1</sup> presents a well organized, detailed description of the present state of knowledge of renal disease. The author follows his well known system of classification of renal disease. Clinical descriptions include numerous case histories, charts, and pathological descriptions. A large bibliography offers opportunities for further study.

Addis<sup>2</sup> has published a thoughtful, personal account of his studies on glomerular nephritis, and of much related experimental work. His book contains a detailed consideration of the clinical features and laboratory evidences of glomerular nephritis, as well as a unique presentation of treatment as applied to an individual patient. In contrast to the usual textbook, the author probes with obvious relish into vast areas of present ignorance about the causation and treatment of nephritis. A number of current physiologic and therapeutic principles emerge somewhat battered from the encounter.

A large part of Addis's book is devoted to the argument for a diet of minimal protein content

throughout the course of glomerular nephritis. "Renal work" in secreting urine consists largely in concentrating urea from a low level in the blood to a high level in the urine. Of course, the kidney does much work of other sorts but the work imposed by a high-protein diet has been repeatedly shown experimentally to be injurious to a damaged kidney. The normal or damaged kidney hypertrophies when the dietary protein is increased. However, when the capacity for urea excretion is exceeded by dietary nitrogen, signs of further renal injury appear in the form of protein, red blood cells and casts in the urine, together with a rising blood pressure and a progressive anemia. These animals die in uremia, which is readily avoidable by the use of a low-protein diet. The same general principle may apply to patients with limited renal function and perhaps to patients who have had an attack of acute glomerular nephritis.

Addis also emphasizes an adequate fluid intake at all times. This serves two purposes: the minimizing of renal work, and the prevention of protein precipitation in the renal tubules. He regards dehydration as dangerous to the patient with proteinuria, a thought to consider before ordering a test of urinary concentrating power. A daily intake sufficient to yield 2 or 3 liters of urine is considered adequate. Above these levels, increases in the fluid intake become less efficient as well as difficult to maintain.

#### Acute Stage

The etiology of acute nephritis is known in general outline, but the specific mechanism remains obscure. The occurrence of several cases in the same family has suggested a "constitutional" predisposition. Addis reports 4 cases of nephritis occurring in only 1 of identical twins. In 1 of these cases the children lived under apparently identical conditions, sleeping in the same room, and each was recovering from a mild attack of scarlet fever when 1 of the twins developed acute nephritis. An essential, nonhereditary factor is strongly suggested by such observations.

Cardozo<sup>3</sup> has recently described an increased volume of the blood in acute nephritis. Addis had suggested that the sudden development of mild anemia and hypoproteinemia, and their reversion to normal levels with diuresis, were due to changes in plasma volume. We have examined this point

\*From the Department of Medicine, Johns Hopkins University School of Medicine and Johns Hopkins Hospital.

Some original work reported here was supported by a research grant from the Division of Research Grants and Fellowships of the National Institute of Health, United States Public Health Service.

†Teaching fellow in medicine, Montreal General Hospital, Montreal, Canada; formerly research fellow in medicine, Johns Hopkins Hospital, Baltimore, Maryland.

‡Associate professor of medicine, Stanford University School of Medicine, San Francisco, California; formerly assistant professor of medicine, Johns Hopkins University School of Medicine, Baltimore, Maryland.

in some detail.<sup>4</sup> During the initial stage, with or without oliguria, the excretion of sodium is greatly depressed. If gastrointestinal symptoms do not block the intake of water and salt, edema develops rapidly. At this stage, the plasma volume is usually increased far above the expected figure. The venous pressure is frequently as high as in cardiac failure, and yet symptoms of failure are not necessarily present. With the onset of diuresis, all these changes may be reversed with astonishing speed. Sodium and water pour out through the kidneys, edema disappears, the plasma volume contracts rapidly, and the plasma protein concentration mounts, sometimes overshooting the mark to a level of 9 or 10 gm per 100 cc. The proportion of albumin is usually unchanged during diuresis, suggesting that there has been a simple concentration of the plasma proteins. When the venous pressure has been elevated, it falls as the edema is eliminated. These findings suggest that retention of salt and water accounts for many of the changes observed in acute nephritis, although doubtless other factors play important roles.

The excellent prognosis in acute nephritis has been emphasized by recent reports.<sup>5-7</sup> Treatment is currently directed at minimizing the physiologic disturbances as they appear. The recently developed antihistaminic drugs suggest the possibility of blocking some effects of the hypothetical antigen-antibody reaction responsible for glomerular nephritis, but only preliminary reports<sup>8</sup> of their successful use have been forthcoming. Penicillin has been very useful in controlling the preliminary infection, and preliminary reports indicate that it may reduce the severity of the ensuing nephritis.<sup>9</sup>

### *Nephrotic Stage*

A comprehensive review of the nephrotic syndrome by Bradley and Tyson<sup>10</sup> recently appeared. The following discussion covers only certain new information in its relation to the nephrotic syndrome.

Many students of the nephrotic syndrome believe that hypoproteinemia can no longer be considered the sole cause of edema.<sup>2, 10, 11</sup> Perhaps the most revealing data came from the studies of treatment of the nephrotic stage with concentrated human serum albumin.<sup>12-15</sup> Albumin has proved to be a safe and frequently effective diuretic, but in most cases, the serum protein concentration is not increased above so-called "critical levels" for edema. The increased circulating albumin draws in fluid to produce a large increase in the plasma volume, clearly demonstrating the Starling effect.<sup>16</sup> When fluid is mobilized from the periphery, however, the excess fluid is not necessarily excreted. The patient may be left with the anomalous combination of a normal total amount of albumin and globulins circulating in his blood, but with double the normal plasma volume and with only half the normal protein concentration. This situation throws

the responsibility for the hydremia and edema directly on the kidney's failure to excrete sodium and water.<sup>17</sup>

The specific difficulty in sodium excretion in the nephrotic syndrome is well recognized. An attempt to reproduce this defect by the classic methods of protein depletion in dogs has been made.<sup>4</sup> Acute plasmapheresis to plasma protein levels around 2.5 gm per 100 cc does not appreciably impair the dog's ability to excrete sodium or water. Chronic protein depletion causes some diminution in excretory function, involving sodium and water to a limited degree. In general, the results do not resemble those found in the nephrotic syndrome, and one is forced to assume that the nephrotic patient's difficulty in the excretion of sodium and water is not due to hypoproteinemia per se. This conclusion is supported by the observation of spontaneous diuresis in nephrosis without a preceding increase in the plasma protein concentration. The depression of sodium excretion in the edematous nephrotic patient may be related to the failure of sodium excretion in acute glomerular nephritis, and may represent a response to this form of renal injury.

Chemical changes preceding a diuresis in a cyclic form of nephrosis have recently been described by Rytand.<sup>18</sup> A rise in urinary alkalinity was the first sign of impending diuresis. Excretion of water preceded the release of sodium and chloride into the urine. We have observed a group of patients with nephrosis who showed a similar lag in the appearance of sodium in the urine, with a corresponding rise in the serum sodium concentration. Excretion of water without sodium may also occur for brief periods at the beginning of albumin treatment in severe nephrosis.<sup>4</sup>

The various forms of treatment of nephrotic edema are critically examined by Thorn<sup>19</sup> in a recent review. The basic measure is the low-sodium diet, abetted by acid-ash diet, acidifying diuretics or potassium salts if renal function permits. If signs of circulatory failure appear, digitalis is indicated. The mercurial diuretics are avoided as potentially dangerous. If renal function is adequate, urea may be given in large amounts by mouth to eliminate fluid from the body, but the fluid intake must be restricted. Amino acids or a high-protein diet is helpful if there has been a prolonged dietary deficit in protein or if the physician wishes to take advantage of the resulting high output of urea, but it requires careful planning to keep the sodium intake low when much protein or amino acids are given. Concentrated human serum albumin for intravenous use has advantages over plasma in its lower sodium content and its freedom from risk of homologous serum jaundice.\* Other

\*Concentrated human serum albumin is now scarce and expensive and one can only hope that voluntary blood donation through the American Red Cross and local programs will furnish adequate supplies of this valuable agent.

protein products are more readily available than albumin, but there are some reservations concerning their use. Southey's tubes remain a very effective means of removing accumulated edema without appreciable risk if careful sterile technic and penicillin therapy are used to eliminate infection. The induction of measles in nonimmune children may initiate a diuresis.<sup>20</sup>

### *Varieties of the Nephrotic Syndrome*

To the difficult differentiation of lipoid nephrosis from the nephrotic stage of glomerular nephritis, Addis<sup>2</sup> adds a third possible choice—a benign, cyclic form of nephrosis. Occurring at any age, a suddenly developing proteinuria is followed by most of the features of the nephrotic syndrome, which may subsequently disappear completely. Recurrences and remissions are seen. Death may rarely occur in the edematous stage, and a few post-mortem studies have shown no glomerulitis. The urinary sediment is not distinctive until after prolonged proteinuria. The urine may return to normal during remission, a finding that Addis regards as incompatible with a diagnosis of glomerular nephritis.

Rytand<sup>18</sup> has observed a cyclic nephrosis following bee sting. Tridione has been implicated as a cause of the nephrotic syndrome.<sup>21</sup> Early syphilis<sup>22</sup> and amyloidosis<sup>23, 24</sup> as causes of nephrosis are the subject of recent reviews.

## CARDIOVASCULAR-RENAL RELATIONS

### *Renal Failure*

The kidney occupies a strategic position in the regulation of the fluid and electrolytes on which the cardiovascular system depends for its normal function. Hypotension and collapse may occur in the "salt-losing nephritis," as well as in Addison's disease, when excessive amounts of sodium and water are lost in the urine.<sup>25</sup> In acute nephritis, the retention of sodium and water is associated with edema, an increased venous pressure and a dilated heart, as well as hypertension. Although the terminal stage of nephritis usually includes hypertension, cardiac embarrassment and retinal-artery disease, the patient with "salt-losing nephritis" usually escapes these complications until the last stages of his illness, when edema may also appear.<sup>25</sup> These observations strongly suggest that the kidney's handling of salt and water may affect the cardiovascular system.

### *Cardiac Failure*

Studies of cardiac failure indicate that the kidney is equally sensitive to failure of its normal cardiovascular support. Warren and Stead<sup>26</sup> have shown that in congestive heart failure, the kidneys fail to excrete salt and water in the normal manner, with resultant edema. They have further demonstrated that this salt retention is due to diminished cardiac

output, and not to venous engorgement of the kidneys or to increased venous pressure, as has long been the accepted view. They point out that the retention of salt and water takes place before there is any demonstrable increase in venous pressure. Merrill<sup>27</sup> states that the decreased volume of glomerular filtrate, combined with normal reabsorption of salt by the tubules, leads to salt retention. Mokotoff, Ross and Leiter<sup>28</sup> have also emphasized the relative constancy of the tubular reabsorptive mechanism for sodium despite variations in glomerular filtration rate. The acute sensitivity of the kidney to shock is described below. It seems quite possible that there is a common, central, regulatory mechanism that is stimulated to conserve sodium and water in an effort to sustain blood volume and cardiac output during cardiovascular emergencies.<sup>29-31</sup>

### *Hypertension*

The renal handling of sodium and water may play a role in "essential" hypertension. Perera and Blood<sup>31</sup> believe that hypertensive patients excrete sodium with some difficulty, owing to abnormal activity of the adrenal cortex. This is based on experiments with a comparative study of normal and hypertensive patients from whose diet salt was withdrawn for twenty-four hours. There was weight loss and diuresis in the control group, but these changes were not observed in the hypertensive patients. Landis and Abrams<sup>32</sup> report that hypertensive rats have an aversion for sodium chloride and bicarbonate, and when desoxycorticosterone is given this aversion is increased. These hypertensive rats did not show any particular appetite for ions supposed to reduce hypertension, such as ammonium, magnesium, thiocyanate and nitrite. These findings support an important role attributed to sodium chloride and the adrenal cortex by Selye,<sup>33</sup> in his general adaptation syndrome and in other observations by Selye and Stone.<sup>34</sup> These developments furnish some foundation for the use of low-salt diets in the treatment of hypertension.<sup>35, 36</sup> It seems likely that the success of Kempner's<sup>36</sup> rice diet is dependent on its low-salt and low-protein content. In this connection, it is interesting to note further observations by Selye's group<sup>37</sup> in which they have shown that the nephrosclerosis induced by the injection of anterior pituitary substance in rats is accompanied by hypertension, and that a low-casein diet is effective in preventing both. They also observed a significant increase in the weight and size of the adrenal glands in animals fed the high-protein diet.

The role of the kidney in the causation of hypertension is still unsettled. It seems clear that renal ischemia can cause hypertension,<sup>38-40</sup> but in the majority of patients, hypertension is not associated with a demonstrable, primary, renal lesion.<sup>41, 42</sup> There is still a real problem in the selection of the

hypertensive patients with unilateral renal disease for nephrectomy. In a recent review of the subject, Smith<sup>43</sup> has analyzed 242 reported cases in which nephrectomy was performed. In assessing the value of operation, only 47 of these met the criteria, which included a clear demonstration of, first, pre-existing hypertension, secondly, reduction of blood pressure to normal levels (140 systolic, 90 diastolic or below) and, thirdly, persistence of blood pressure at this level for a year or longer. Smith considered the operation successful in 19 per cent of the cases. Sabin<sup>44</sup> has reviewed 106 cases in which nephrectomy was performed for hypertension associated with unilateral renal disease. Pyelonephritis was the commonest offending pathologic lesion (45 per cent of the total), as in Smith's series. In Sabin's group, the blood pressure became normal in 51 patients, reduced in 23 and unchanged in 26—a more successful result than that in the cases reported by Smith, largely because of variations in criteria. Landley and Platt<sup>45</sup> have evaluated a similar group of patients. Smith concludes that the advisability of nephrectomy must rest upon conservative and recognized surgical indications, and not upon the hope of reducing blood pressure. If bilateral disease is present (and it usually is present in advanced hypertension), as a result of the hypertensive process itself, nephrectomy may shorten life by removing an important fraction of total available renal function.

#### RENAL DISEASE IN DIABETES MELLITUS

Robbins<sup>46</sup> discusses a group of conditions of frequent occurrence in diabetes, including glycogen nephrosis, nephrosclerosis, intercapillary glomerulosclerosis, pyelonephritis and necrotizing papillitis.

Glycogen nephrosis is a benign renal change limited to diabetic patients and those with von Gierke's disease (glycogenosis). In general, the presence of this finding at autopsy is dependent upon terminal control of the diabetes and not so much on the severity of the diabetes.

"Benign nephrosclerosis" is a frequent finding especially in older patients with hypertension. It occurs in a relatively younger age group and runs a more serious course in patients with diabetes.

Intercapillary glomerulosclerosis as defined by Robbins occurs only in diabetes, although closely allied pathological changes are found in nondiabetic persons. Kimmelstiel and Wilson's<sup>47</sup> cases were examples of the nodular type, which probably does not occur without diabetes.<sup>48</sup> A similar glomerular lesion occurring in diabetes mellitus is the diffuse type, which bears a close resemblance to changes seen in chronic glomerulonephritis and in nephrosclerosis.

Most recent observers agree that it is not easy to make the diagnosis clinically.<sup>46, 48-50</sup> Long duration of diabetes predisposes to the renal change, although the diabetes need not be severe. Hyper-

tension is of little diagnostic significance in an older diabetic patient. Albuminuria is also a common finding, but profuse albuminuria indicates a probable glomerular lesion. Hypoproteinemia and edema favor intercapillary glomerulosclerosis, but occur in only a small proportion of cases. Slowly developing renal insufficiency and a mixed vascular and diabetic retinopathy may be present. Robbins<sup>46</sup> suggests that a correct diagnosis can be made clinically in 60 per cent of the cases. In a recent report, Adams<sup>50</sup> discusses 5 interesting cases in young diabetic patients that fit the clinical criteria, but the pathologic lesions were found to be a combined inflammation and vascular hyaline degeneration.

Acute pyelonephritis is four and a half times more common a cause of death in diabetic than in nondiabetic patients, and 1 in 5 diabetic patients at autopsy shows some acute pyelonephritis.

Necrotizing renal papillitis is a peculiar form of pyelonephritis with massive necrosis of the renal pyramids, frequently involving all pyramids of both kidneys. Edmondson, Martin and Evans,<sup>51</sup> in a series of 859 diabetic patients, discovered 29 patients with renal papillitis, an incidence of 3.4 per cent. The organisms most commonly noted were *Escherichia coli* and *Staphylococcus aureus*, but *Mycobacterium tuberculosis* and actinomycetes were each found once. In the same series of 32,000 autopsies, these workers observed pyelonephritis in 1023 nondiabetic patients, of whom 21 had lesions characteristic of papillary necrosis. In 20 of these it was a complication of urinary-tract obstruction. Robbins, Mallory and Kinney<sup>52</sup> discussed 26 cases, 19 of the patients had diabetes, and all except 1 of the seven nondiabetic patients had an associated urinary-tract obstruction. Mallory, Crane and Edwards<sup>53</sup> have produced similar lesions in rabbits by ligating one ureter and injecting suitable pathogenic organisms into a vein. The lesions appeared only in the obstructed kidney.

The symptoms of necrotizing renal papillitis may be acute, with sudden onset of prostration, septic type of fever, tachycardia, leukocytosis, pyuria, oliguria, azotemia and a fulminating course ending in death within three or four days. In other cases, a subacute, protracted type appears, characterized by weeks or months of purulent pyelonephritis, with a terminal exacerbation resembling the acute form of necrotizing papillitis. Richfield<sup>54</sup> and Stevens et al.<sup>55</sup> have reported cases, the latter group including an interesting review of the subject.

Edmondson and his co-workers<sup>51</sup> suggest that criteria for diagnosis of necrotizing papillitis in diabetes should include hematuria, renal colic, sudden appearance or aggravation of pyelonephritis and signs of sepsis or unexplained coma. Earlier, Mellgren and Redell<sup>56</sup> also described colic, explained by obstruction of the ureter by a sloughed papilla.

Characteristic roentgenographic signs have been reported by Allen,<sup>57</sup> who describes a cavity-like enlargement and deformity of the calyces in the pvelogram, resembling the findings in some types of renal tuberculosis. Edmondson<sup>51</sup> has more recently emphasized this point.

The early recognition of this serious complication, and the prompt institution of therapy may give the patient some chance of recovery.

#### IRRADIATED STEROL POISONING

This type of renal injury must be considered in any cases of uremia of obscure origin, and a history of joint pains and vitamin treatment should be sought. The widespread use of large doses of potent irradiated sterols for arthritis has made hypercalcemic renal insufficiency no longer a rarity.<sup>55, 59</sup> There is a wide individual variation in susceptibility to these products. Anorexia, nausea, abdominal pain and muscular weakness may give warning of a rising serum calcium. Prolonged hypercalcemia may lead to metastatic calcification of many tissues. Walsh and Howard<sup>60</sup> have recently described glistening deposits in the conjunctiva and cornea, visible under the slit-lamp, developing soon after a rise of the serum calcium.

Polyuria is often the first symptom of renal involvement. The urine is usually dilute and may contain no trace of albumin. Microscopical examination of urine may show casts containing black granules, which dissolve in acid. The finding of a grossly elevated blood urea may come as a surprise with such a benign urinalysis. If Sulzowitch's<sup>61</sup> simple test is applied to the urine, the hypercalciuria is at once apparent. The mystery is quickly solved when the patient is questioned specifically about vitamin D ingestion. Hyperparathyroidism must be considered if no history of medication can be obtained, and may raise a difficult diagnostic problem, since the serum calcium subsides very slowly in some patients when vitamin D is withdrawn. The normal condition of the bones and the high level of serum phosphate after vitamin D administration may be helpful.

#### RARE RENAL LESIONS

Interesting cases of renal involvement by poly-cystic disease,<sup>62-64</sup> periarteritis nodosa,<sup>65</sup> sarcoidosis<sup>66</sup> and sickle-cell disease<sup>67</sup> have been reported.

#### ACUTE RENAL-TUBULE INJURY

Lower-nephron nephrosis is the term designated by Lucké<sup>68</sup> to describe the renal lesions produced by a wide variety of traumatizing conditions that have in common the main feature of shock. Harkins<sup>69</sup> has listed more than 30 causes of shock, including trauma, burns, freezing, vascular occlusion, intestinal strangulation, bile peritonitis, visceral perforation, toxic drugs, venoms, anaphylaxis, transfusion reactions and fulminating infec-

tions. It is possible for renal lesions to develop secondarily to any one of these. Indeed, numerous recent reports<sup>70-74</sup> indicate the diversity of the etiologic factors, including many of those listed above.

Harman<sup>71</sup> has reviewed 1065 autopsies of battle casualties and found evidences of lower-nephron nephrosis in 152, or 14.2 per cent. Of these, 70 patients had died of renal insufficiency. The exciting causes included vascular damage, muscle trauma, crush, transfusion reaction, hemorrhage, burns, gas gangrene and shock. He also observed that the administration of sulfonamides had not increased the incidence or severity of the nephrosis.

Tagnon and his co-workers<sup>72</sup> have reviewed the situation regarding burns. They report 450 patients who lived more than two weeks after the burn and showed no evidence of lasting kidney dysfunction. On the other hand, of 35 patients who died less than two weeks after the burn, 14 had definite clinical and pathological evidence of renal injury. Martineau and Hartman,<sup>73</sup> in a combined experimental and clinical study of burns, conclude there is a close relation between the "burn" kidney and the renal findings of other conditions characterized by intravascular hemolysis.

In relation to shock from trauma and burns, Fox and Baer<sup>75</sup> have correlated death with extrusion of considerable potassium from injured cells and their acquisition of an equivalent amount of sodium. They believe that this exchange results in swelling of uninjured tissue cells throughout the body, leading to additional reduction in extracellular fluid and blood volumes.

Sanderson<sup>74</sup> has reported 4 cases of renal insufficiency following abdominal catastrophe in which he believed that dehydration played a dominant role.

Corcoran, Taylor and Page<sup>76</sup> and, more recently, Kugel<sup>77</sup> have used the term "acute toxic nephrosis" to apply to cases that are primarily the result of poisoning or from hemolytic transfusion reaction. Many such cases have been reported. Bock et al.<sup>78</sup> have reported a case due to sulfadiazine; Woods<sup>79</sup> and Kugel<sup>77</sup> cases due to carbon tetrachloride, Anderson<sup>80</sup> a case of renal damage resulting from sensitivity to neoarsphenamine, and Corcoran, Taylor and Page<sup>81</sup> cases of vitamin D intoxication and mercuric bichloride poisoning.

The renal lesions occur in a similar region in all these cases, with selective tubular damage to the ascending loops of Henle and the distal tubules. The glomeruli and proximal tubules are only indirectly affected. These pathological findings have been described by Lucké,<sup>68</sup> Mallory,<sup>82</sup> Bywaters<sup>83</sup> and others. Woods<sup>79</sup> has remarked on the similarity of the renal changes in the crush syndrome and carbon tetrachloride poisoning.

The mechanism of the production of this renal injury has been the subject of much experimental

work Corcoran and Page<sup>84</sup> showed that shock and early hypotension from bleeding resulted in renal vasoconstriction, and that subsequent raising of the arterial blood pressure and blood volume by transfusion failed to restore the indirectly determined renal blood flow to more than 50 per cent of normal. In an earlier work, Page<sup>85</sup> suggested that the vasoconstrictive ischemia is of humoral origin. In this connection, Little, Green and Hawkins,<sup>86</sup> in crossed-transfusion experiments with shocked and normal dogs, were unable to observe any impairment in urine formation that could be attributed to the operation of a humoral factor and concluded that it was probably due to a lowering of the mean arterial pressure together with homeostatically induced renal vasoconstriction.

Corcoran and Page<sup>84</sup> summarize the sequence of events as follows: vasoconstrictive renal ischemia occurs with onset of shock or injury and more or less myoglobin diffuses into the blood from the crushed area and is filtered into the renal tubules; pigmentary precipitation may then occur and is facilitated by the presence of a urine that is acid and of small volume. Bywaters<sup>83</sup> and Mallory<sup>82</sup> agree that the formation of precipitated material in the tubules may contribute to the progress of the lesions once they are initiated by renal ischemia, though they do not believe that mechanical obstruction is the cause of renal failure. Lucké<sup>88</sup> states that in many of his cases he found few pigment casts and points out that in the anuria of shock the urine is of low specific gravity and small volume, indicating a more general renal lesion. In this connection, Yuile, Gold and Hinds<sup>87</sup> conclude that the precipitation of hemoglobin in the renal tubules is primarily dependent on antecedent damage to the tubules and not on the acidity or alkalinity of the urine or the amount of hemoglobin in the blood.

The similarity of the lesions produced by nephrotoxic substances and shock has led Lucké to suggest that the cause of renal insufficiency is the same in both conditions. It is generally agreed that renal ischemia is the first step.<sup>88, 89</sup>

#### NEURAL CONTROL OF THE RENAL CIRCULATION

An important new description of the renal circulation promises to shed light on some of these obscure problems in renal dysfunction. Trueta et al.<sup>90</sup> present convincing evidence of a dual circulation to the kidney under the control of the autonomic nervous system. The work began with arteriograms of the hind limbs of rabbits after a simulated crushing injury. Arterial spasm was demonstrated not only at the level of the injury but also extending proximally and sometimes into the opposite limb. The renal arteries were found to be singularly sensitive to this reflex spasm, which persisted for hours after the injury. The blood pressure did not fall enough to account for such a compensatory vasoconstriction. It was found that

stimulation of afferent sciatic-nerve fibers, of efferent splanchnic-nerve components or of fibers about the renal artery caused renal-artery spasm. Other effective stimuli were rapid hemorrhage, large doses of epinephrine or pitressin and the injection of staphylococcus toxin.

In an excellent series of radiographs and pigment injections, Trueta and his co-workers demonstrated a striking diversion of intrarenal blood flow from the cortex to the medulla of the kidney during the various procedures used to excite the renal-artery spasm. The blanching of the cortex was observed directly on the exposed kidney. The renal blood flow did not stop, but the renal vein sometimes took on a bright-red color and a pulsatile flow. The rapid renal-circulation time as measured by dyes suggested that an actual shunt of blood through the medullary circuit might occur.

The arterial spasm affecting the outer two thirds of the cortex failed to impair the circulation to the innermost glomeruli. These juxtamedullary glomeruli were dilated, and supplied the first link in the medullary shunt, which then continued through the vasa recta deep into the medulla. The vasa recta mingled freely with the long loops of Henle arising from the deeper glomeruli. It is suggested that this is an ideal site for water reabsorption, and that the diversion of circulation to the medulla may lead to oliguria or even to anuria.

Most of these experiments were done in rabbits, which are known to have a very labile renal circulation, but the work has now been extended to several other mammals and doubtless will soon be tested in man. Normal men have a very steady rate of glomerular filtration, but there is evidence that disease may modify this picture. In particular, hemorrhagic shock is known to affect renal clearances out of all proportion to the fall in blood pressure.<sup>88</sup> In dogs, the clearance of para-amino hippuric acid, which usually measures renal blood flow, may be depressed well below the actual renal flow for prolonged periods, even after blood transfusion has increased the blood pressure to normal levels.<sup>84</sup> Collateral evidence<sup>84, 88, 89</sup> points strongly to a redistribution of circulation through the kidney in hemorrhagic shock and may indicate the presence in man of a shunt such as Trueta and his co-workers have demonstrated. It also seems likely that reflex and hysterical anuria may depend on renal vasoconstriction. The importance of ischemia of the renal cortex in the development of the crush syndrome and allied states has already been pointed out.

Diseased kidneys may contain juxtamedullary glomeruli that have degenerated into little more than direct passages for the escape of blood from the arteries to the vasa recta. Trueta and his co-workers suggest that these are produced in some cases by repeated reflex diversion of the blood through the medullary circuit. If such changes could follow emotional stress, a possible explanation

tion for the development of cortical ischemia and of a chronic hypertension might be imagined. Endless fields for speculation on the possible effects of the reflex control of the renal circulation are opened up, and further experimental studies are eagerly awaited.

#### TREATMENT OF ACUTE RENAL INSUFFICIENCY

Therapy is considered in three stages: immediate, specific treatment to minimize damage, regulation of fluid and electrolyte balance, and dialyzing procedures to reduce azotemia.

##### Initial Measures

The first aim of therapy is to limit the extent of damage as far as possible. The first measure is replacement of lost blood and fluid in cases of severe shock, and pressure bandaging of the affected part before removal of the tourniquet in cases of trauma.<sup>84</sup> It is during this period of the first few hours that renal ischemia is present and renal blood flow and renal function are reduced.<sup>88, 89</sup> Dogs can tolerate complete renal-artery occlusion for as long as two or three hours without irreversible damage.<sup>91, 92</sup> The timing of blood replacement is of utmost importance to the ultimate outcome, since in the earliest stages serious renal injury may be avoided.

In the nephrotoxic cases, the immediate exclusion or neutralization of the offending agent is of prime importance. Alkalinization of the urine is valuable in the prevention of renal injury by sulfonamides, and may be useful in transfusion reaction, although there is still difference of opinion about the efficacy of this. Thus, Flink<sup>93</sup> reports that in dogs the excretion of hemoglobin proceeds at about the same rate and produces approximately the same renal damage whether the urine is acid or alkaline. On the other hand, Fox et al.,<sup>94</sup> Corcoran and Page<sup>84</sup> and others recommend the alkalinization of the urine after transfusion reactions. Clinically, the use of alkali appears of limited value unless given early and in adequate dosage.

BAL<sup>95</sup> may be life saving in mercuric bichloride poisoning, but prompt institution of therapy is important. Most patients have recovered despite very large doses of mercuric chloride, when BAL was given in adequate dosage within four or five hours after poisoning. When treatment is delayed for six hours, the effectiveness of BAL is much less striking. Sodium formaldehyde sulfoxylate is recommended for lavage of the stomach, to inactivate unabsorbed mercuric chloride.

##### Fluid and Electrolyte Balance

When a patient is found to be passing no urine, and when obstruction of the urinary tract has been ruled out, there is a natural impulse to force fluids to "open up the kidneys." Dehydration and shock are strong indications for immediate parenteral therapy, but often the treatment is continued too

long and too vigorously when no urine is excreted. After some days of heavy intravenous fluid therapy, the patient is edematous, circulatory failure may be imminent, and frequently the concentration of sodium and chloride in the plasma is depressed to dangerous levels.

The error in treatment arises from failure to recognize the elementary fact that *the anuric patient cannot excrete water* except in very limited amounts in breath, sweat and stools. There is every reason to establish a normal circulation and state of hydration, but there are equally cogent reasons for not exceeding the normal range of fluid volume. Another liability of the anuric patient is his inability to excrete potassium, which slowly increases in concentration in the plasma until dangerous or fatal levels are reached.

Hope must not be lost even when the outlook seems darkest, for diuresis may begin at any time if the patient is kept in good condition. Since the renal injury is usually self-limited, a remarkable restoration of function occurs if the patient can be tided over the critical period.

Thorn<sup>19</sup> has outlined a program to be followed during this phase.

The careful restriction of fluids so that no gain in body weight is observed during the period of anuria. In most patients 1000 to 1500 cc of fluid for twenty-four hours is adequate in the absence of fever or fluid loss from vomiting, diarrhea or other causes.

The provision of as high a caloric intake as possible during the early stage of anorexia and vomiting, 15 per cent glucose solution as an infusion will reduce endogenous protein breakdown.

The use of small quantities of plasma ( $\frac{1}{2}$  unit) or normal human serum albumin (10 to 15 gm daily) in the glucose solution to maintain blood volume and to prevent to some extent excessive fluid dissipation into the extracellular spaces. Intravenous albumin and plasma may reduce endogenous nitrogen breakdown somewhat.

Digitalization at the first evidence of cardiac enlargement or pulmonary congestion.

The quantity of sodium chloride to be given each day should be planned to keep a normal concentration of these electrolytes in the plasma. Kugel<sup>77</sup> suggests 5 or 6 gm per day to supply the approximate amount required daily by the normal person and that this amount be increased or decreased according to the state of hydration. He also points out that marked tissue weight loss occurring during this period may release a large volume of intracellular fluid, which aggravates the edema.

By this conservative routine, spontaneous diuresis may be effected on the tenth to the twelfth day in many cases, especially the less severe ones, and the

patients will go on to recover Thorn<sup>19</sup> and Kugel<sup>77</sup> have reported cases in which such recoveries have taken place

In the severe cases such an outcome may occur, but resort to more radical means of correcting the azotemia and electrolyte unbalance may become necessary These procedures are discussed below

### *Phase of Diuresis*

Burwell, Kinney and Finch<sup>96</sup> point out that the second peak in the mortality rate in cases of intravascular hemolytic crises occurs on the tenth day regardless of the fact that many of the patients had shown a spontaneous diuresis at that time Thorn<sup>19</sup> suggests that this is related to the development of hypochloremia and subsequent dehydration at a time when the renal lesion is actually improving but normal function has not been completely established Large amounts of sodium chloride and water may be required during this period, or, in rare cases, water without salt must be given<sup>97</sup> The amount can only be determined by close examination of the serum chloride and bicarbonate levels until the kidney has recovered its normal regulatory functions

### *Artificial Kidney*

With the increased incidence and recognition of lower-nephron nephrosis and toxic nephrosis during recent years, there has been a strong impetus to further the clinical application of the original work done by Abel, Rowntree and Turner<sup>98</sup> in the removal of diffusible substances from the blood by dialysis Several methods have been evolved by different investigators and applied clinically with varying degrees of success

Kolff,<sup>99</sup> Alwall<sup>100</sup> and Murray<sup>101</sup> have developed "artificial kidneys" and applied them successfully in many cases of renal failure They differ in some respects, but all use cellophane as the membrane to remove diffusible crystalloids from the blood to the exterior as well as to maintain the normal concentration of the essential components of the blood

Kolff<sup>99</sup> has recently reviewed some of his results Of the first 15 patients on whom the artificial kidney was used, 14 died, and of the next 16, 10 died These apparently disastrous results were due to the high percentage of chronic renal disease, in which any improvement could be only temporary On the other hand, he cited several cases of successful treatment of uremia in patients with acute glomerulonephritis and mercuric bichloride poisoning

Alwall<sup>100</sup> claims that his dialyser is superior to that of Kolff and lists advantages to support his view the apparatus is small, all the cellophane is in contact with saline solution, the blood does not have to pass the rotation cylinder, arterial pressure is the driving force lessening the incidence of hemolysis, there is less risk of coagulation, heparin

dosage is reduced, and there is therefore less tendency to hemorrhage, and the blood pressure does not fall, and therefore there is no shock Certainly, the reduction of hemorrhage and shock would be important advances Alwall has reported successful cases in which his apparatus was used, both experimentally and clinically

Murray<sup>101</sup> has had good results with his artificial kidney in experimental work One of his clinical cases with renal shutdown secondary to an induced abortion is particularly enlightening Repeated use of the artificial kidney kept the patient alive until the kidneys were able to secrete urine, and progressive recovery ensued As much as 66 gm of nonprotein nitrogen was removed with a single period of dialysis

In contrast to these generally successful reports, Muirhead and Vanatta<sup>104</sup> have tested the artificial kidney experimentally on dogs, and, after disastrous results, concluded that in its present form it is not ready for clinical application

At present, the artificial kidney appears to be a promising therapeutic instrument for treatment of acute renal insufficiency, but its use is not without risk It requires a trained medical and technical team for effective performance

### *Peritoneal Dialysis*

Suggested many years ago by Ganter,<sup>105</sup> peritoneal dialysis has recently been reintroduced by Seligman, Frank and Fine<sup>106, 107</sup> in the treatment of acute renal failure Fine, Frank and Seligman<sup>106</sup>, Goodyear and Beard<sup>108</sup> and Muirhead et al,<sup>109</sup> to mention a few, have reported successful application of this method to the treatment of uremia following incompatible blood transfusion Bloxson and Powell<sup>110</sup> have successfully treated a case of uremia concomitant with acute glomerulonephritis, and Pearson<sup>111</sup> reports its trial in a case of carbon tetrachloride poisoning Marsden<sup>112</sup> has reported its use in an interesting case of eclampsia Odel and Ferris<sup>113</sup> give an excellent review of 27 cases collected from the literature and report 1 case of their own

The clinical application of this form of treatment is becoming a widely accepted procedure, but it requires careful planning to avoid the pitfalls of water and electrolyte unbalance, of infection, and of poor timing The dialyzing fluid must be prepared in great volume The addition of sodium bicarbonate and antibiotics just before the fluid is used is clumsy and increases the possibility of contamination The composition of the fluid must be carefully planned to contain all the ingredients of the plasma, but its composition may have to be changed to meet individual needs Glucose is added to prevent the loss of blood sugar, and as an osmotic balance to avoid undue absorption of water The best method of use of antibiotics is still unsettled, and peritonitis is a definite risk Heparin is usually added to the fluid to slow the deposition of fibrin,

but the efficiency of dialysis falls off rapidly after three or four days

Muirhead, Small et al<sup>114</sup> report 3 cases in which they encountered one or another of these complications. In 1 case too much sodium chloride was absorbed, and the edema increased until distilled water was substituted and 70 gm sodium chloride subsequently removed in this way with copious diuresis following. In another case, after a transfusion reaction, peritoneal irrigation was begun early in hopes of preventing the development of azotemia. This condition was not avoided, however, and the renal lesion progressed in spite of irrigation, and edema and acidosis were continuous worries. A third case was also complicated by severe acidosis and edema. Rob and Richardson<sup>115</sup> have likewise emphasized these points. Robertson and Rutherford<sup>116</sup> have encountered pulmonary edema in a patient dying on the eighth day.

To combat some of these complications, Reid, Penfold and Jones<sup>117</sup> have successfully used intermittent peritoneal irrigation. This may prevent the formation of a channel between entrance and exit tubes, which often takes place with continuous irrigation.

For control of peritonitis, most authors recommend the addition of penicillin, streptomycin or sulfonamides to the fluid, but Reid<sup>117</sup> has discarded penicillin as having an irritating effect on the peritoneum, which, by causing exudation, might interfere with free osmosis.

In summary, it may be said that peritoneal irrigation should be reserved for cases of acute renal insufficiency in which the process is likely to be reversible and only after more conservative measures have failed.

### *Intestinal Lavage*

In an effort to find a safe, effective means of dialyzing water and crystalloids across a membranous surface of the body, numerous investigators have used various segments of the gastrointestinal tract.

Kolff<sup>118</sup> and Daugherty, Odel and Ferris<sup>119</sup> have concluded that the colon is unsuitable as a dialyzing membrane in the treatment of uremia, but an isolated loop of small intestine can be used with more success. Seligman, Frank and Fine,<sup>120</sup> after comparative studies in animals, concluded that the jejunum is probably the most suitable segment of the intestine for dialysis.

Most of these authors<sup>106, 118-121</sup> have perfused various segments of the gastrointestinal tract in treating patients with uremia. The results do not seem to be as encouraging as those with peritoneal lavage, but the procedure has not been so widely applied and many technical difficulties have to be overcome.

### *Renal Decapsulation*

One of the numerous theories proposed to explain renal failure in toxic nephrosis is a decrease of the effective filtration pressure as a result of increased intrarenal pressure. Peters<sup>70</sup> recommends early decapsulation in severe cases and states that this procedure reduces the intrarenal pressure by 50 per cent. One point against this theory is that it does not explain the spontaneous diuresis on the tenth to the twelfth day when fluid retention is maximum. A more reasonable relation to the onset of the diuresis appears to be the fact that the tubular epithelium begins to regenerate soon after injury and is often adequately healed by the fourteenth day. Reports of a few cases successfully treated by this method have recently appeared in the literature including one by Reid, Penfold and Jones<sup>122</sup> in which peritoneal irrigation was combined with renal decapsulation.

Culpepper and Findley,<sup>123</sup> in an excellent review of the subject, discuss numerous cases of decapsulation and report an over-all mortality of about 50 per cent. They suggest that decapsulation of one kidney is as effective and less dangerous than a bilateral operation.

### *Spinal Anesthesia or Splanchnic Block*

Trueta and his co-workers<sup>90</sup> have clearly demonstrated that reflex stimulation of the splanchnic nerves can divert the renal circulation from the cortical glomeruli. After section of the splanchnic nerves, this effect is reversed, and injury leads to a dilated cortical circulation. It is suggested that renal failure in the crush syndrome and allied conditions are of neurogenic origin and that they should be treated by spinal anesthesia or splanchnic block.

Several recent reports describe successful use of these methods in the treatment of acute renal shutdown. O'Sullivan and Spitzer<sup>124</sup> have successfully treated 2 cases of postabortion anuria with spinal anesthesia. Williams<sup>125</sup> reports a case of renal failure due to Weil's disease, in which diuresis continued after the effects of spinal anesthesia had worn off. This patient went on to recover. Robertson<sup>126</sup> has reported 3 cases of renal failure secondary to Weil's disease treated by this method, with 1 recovery and 2 deaths. In the fatal cases, the spinal anesthesia was carried out very late in the course of the disease.

Hingson and his co-workers<sup>127</sup> have had some interesting results with continuous caudal and spinal anesthesia, 35 patients suffering from anuria due to various causes, including eclampsia and acute vascular accidents, were treated. There were 8 deaths, 2 being among eclamptic patients, and in 2 it is possible that the splanchnic block contributed to the fatal outcome. It seems possible to keep up a continuous block for ten days, — that

is, to the crucial period, — after which the kidneys may resume normal function

\* \* \*

These observations bring out the important interdependence of the cardiovascular system, the autonomic nervous system and the kidney, and emphasize the need of consideration of the whole group of organs in renal malfunction or injury. Only rarely can an established renal injury be modified, but, guided by chemical and physiologic data, one can tide some patients over a critical period of renal insufficiency.

#### CASE 34431

##### PRESENTATION OF CASE

*First admission* A seventy-six-year-old woman was admitted to the hospital because of "pains in the stomach."

For many years the patient had attacks of momentary knife-like pain in the left upper quadrant of the abdomen, which never caused her much concern. About ten months before entry, however, she was confined to bed for three days with repeated attacks, each lasting about half an hour. These began with a sharp "ball of pain" in the left upper quadrant of the abdomen, which moved toward the epigastrium, "stabbing" as it went and accompanied by much gurgling. The pain then passed off. Also at that time she had a "large, black, slimy discharge" from the rectum. She had no nausea or vomiting. She was then well except for occasional pains until one month before admission, when she again had a three-day attack of the same type of pain. One week later she passed a tarry stool. She never tried food or alkali for relief of the pain, and she did not notice any loss of strength or energy during the present illness. She noted no difference in the character of the pain upon sitting or lying down.

Her appetite had been poor for eight years before admission, the change having been noted about the time of a "nervous breakdown," which followed her husband's death. She was put on a diet at that time and ate no vegetables, raw fruits, fried or fatty foods.

Physical examination revealed a woman in no acute distress but showing some evidence of weight loss. The blood pressure was 190 systolic, 80 diastolic. The rest of the examination was essentially negative.

Examination of the blood disclosed a white-cell count of 10,800, with 71 per cent neutrophils. The hemoglobin was 13.2 gm per 100 cc. The red cells and platelets were fairly normal in appearance. The total protein was 7.1 gm, and the nonprotein nitrogen 26 mg per 100 cc. The urine specific gravity was 1.016, and the sediment contained 3 white cells per high-power field. A stool was guaiac negative.

A barium enema revealed numerous diverticula throughout the entire length of the colon but more marked in the descending and sigmoid portions. There was a redundancy of the hepatic flexure of the colon, and the cecum lay high and was directed laterally. About 5 cm from the cecal tip there was a constant constriction of the lumen over a length of about 2 cm (Fig 1). The mucosa within the lumen did not appear to be destroyed. The terminal ileum was not seen. A Graham test and an intravenous pyelogram were negative. A gastrointestinal series showed a normal esophagus with the patient in the erect position. However, with the patient in a prone position a large, readily reducible hiatus hernia was demonstrated, the cardia being situated above the diaphragm. The diaphragmatic hiatus was of good size but constricted the fundus slightly. No lesion was demonstrated within the herniated portion of the stomach, and the remainder of the stomach and duodenum was not remarkable. The small bowel was normal, the ileocecal region was not well shown.

After a stay of two and a half weeks in the hospital the patient was discharged to return in two months for another barium enema.

*Second admission* (approximately two months later). In the interval the patient had felt improved although she did not find the prescribed diet palatable. She had two attacks of crampy, sharp pain in the left upper quadrant of the abdomen, each lasting about three days and unassociated with nausea, vomiting, diarrhea or constipation. She had no tarry or bloody stools.

Physical examination showed, in addition to the findings of the first admission, slight tenderness in the left upper quadrant of the abdomen. The cecum was questionably palpable. The abdomen was protuberant and tympanitic, with hyperactive peristalsis of moderately high-pitched character.

Examination of the blood disclosed a white-cell count of 9300, with 74 per cent neutrophils. The hemoglobin was 9.7 gm. The stool was guaiac negative.

A plain film of the abdomen showed a suggestion of fullness overlying the sacrum extending somewhat to the right and about which ran a loop of small bowel. A barium enema revealed no abnormalities except diverticula until a redundant hepatic flexure was passed and the distal portion of the ascending colon entered. There the barium encountered an obstruction with narrowing of the lumen of the bowel but with many mucosal folds still apparent in that region. A gastrointestinal series confirmed the previous finding of a hiatus hernia that filled and emptied well. The remainder of the stomach was normal, as was the small bowel, with the exception of one persistent loop in the right lower quadrant, which appeared to be held in relatively constant position by an oval mass in the right lower quadrant (Fig 2). The proximal

portion of the large bowel demonstrated a constricting lesion in the ascending colon at the level of the apparent mass that fixed the small bowel

On the twelfth hospital day an operation was performed

### DIFFERENTIAL DIAGNOSIS

DR RICHARD SCHATZKI I have been given a large number of films and have selected some of them for demonstration I am in the position of the radiologist who has to rely on films of the gastrointestinal tract that somebody else has taken and somebody else has seen the fluoroscopy and taken spot films If that person did not see the actual lesion, I am out of luck because I will not have films of the lesion If he has seen it and has taken inadequate films, I am still in trouble I am probably in trouble anyhow

In summarizing the history one can say that in ten or twelve months this woman had two attacks of severe left-upper-quadrant pain, bled twice and ended up by having a slight anemia

As far as the question of bleeding is concerned, I have a spot film of the lower end of the esophagus that fails to show varices, and since I cannot see

bleeding because I am convinced that it is not a very common source of massive bleeding So for the sake of this discussion I am going to say that I do not believe that this patient bled from a hiatus hernia

The patient had numerous diverticula in the colon Diverticulosis, particularly diverticulitis of the colon, is supposed to cause hemorrhage Again, I am unhappy if I cannot find any other source of bleeding in a patient but diverticulosis or diverticulitis The recent surgical literature talks about bleeding in diverticulitis as if it were very common Personally, I am convinced that it is not common

FIGURE 2

FIGURE 1

any in the film, I am not going to think any more about them The most common source of bleeding in a patient with tarry stools is duodenal ulcer There are a few spot films of the duodenum that do not show any abnormality Although it is possible that on such films an ulcer might be missed, I am going to discard this diagnosis Hiatus hernia is a source of bleeding I am usually, however, not satisfied to accept a hiatus hernia as the source of

although it does occur I do not believe that this patient bled from diverticulosis, particularly since she had tarry stools

I would like to find something in this patient's left upper abdomen In looking through the films I have not been able to see anything there that might cause the symptoms

Some other things might be mentioned She had extensive arteriosclerosis of the abdominal aorta and its branches She had changes in the left femur that were probably due to Paget's disease

So we come to the ileocecal region — the lesion described in the record is not an area that one can understand from the films that we have The abnormal position of the ascending colon is seen The tip of the cecum, if this is the tip, is not the lowest point of the right colon but lies posteriorly

The remainder of the stomach was normal, as was the small bowel, with the exception of one persistent loop in the right lower quadrant, which appeared to be held in relatively constant position by an oval mass in the right lower quadrant (Fig 2). The proximal

## ANATOMICAL DIAGNOSIS

*Carcinoid of ileum.*

## PATHOLOGICAL DISCUSSION

DR CLAUDE E. WELCH I must congratulate Dr Schatzki on his diagnosis. This was a very difficult problem clinically. When the patient first came to the hospital we thought that her symptoms were due to diaphragmatic hernia, accounting for the left-upper-quadrant pain and, apparently, for the gastrointestinal bleeding. She had, in addition, this defect in the cecum. Our attention was focused high on the ascending colon over this area seen in the first film, which I thought could be due to adhesions around an old diverticulitis. The question arose whether to operate on the strength of this x-ray finding or whether, at the age of seventy-six, she might be relieved by diet. We therefore sent her home for a two-month period to return for further evaluation. She modified her diet to the point where it included only water, which probably accounted for the secondary anemia, since the stools remained guaiac negative. Since at the second admission the same defect in the cecum was manifested and she did have an episode of distention, it seemed wise to explore her. At operation there were numerous adhesions in the right lower quadrant, a diaphragmatic hernia and diverticulitis. The remainder of the abdomen was normal except for the region of the ileocecal valve, where, in the midst of the adhesions, was a rather indefinite palpable mass. One definitely dilated loop of the terminal ileum was tied up in the adhesions. The rest of the small bowel was entirely normal. I did a right colectomy on her in one stage. Dr Mallory will give us the final report. It is only fair to state that we do not know yet whether or not the pains will be relieved by the operation. She is relieved of the disease in the right lower quadrant. The pain may have been due to the diaphragmatic hernia.

DR SCHATZKI How often does pain in the left upper quadrant occur with a diaphragmatic hernia?

DR WELCH The pains were repeated, postprandial attacks. It is not too uncommon to have pain of that type with diaphragmatic hernia.

DR MALLORY The lesion that Dr Welch resected was in the terminal ileum, immediately adjacent to the ileocecal valve. It was a tumor lying in the submucosal wall of the ileum. It extended through the wall into the mesenteric fat, and it had produced numerous adhesions. There was no actual tumor of the cecum. The tumor histologically was characteristic of carcinoid. There were numerous enlarged mesenteric lymph nodes, but none of them showed metastases. These carcinoids of the ileum do actually metastasize but usually not to any great distance. Not infrequently they metastasize to the immediately adjacent mesenteric lymph nodes.

DR SCHATZKI What caused the bleeding?

DR MALLORY There was no evidence of ulceration of the mucous membrane overlying the tumor, and I am not at all sure that we have an explanation for the bleeding.

DR SCHATZKI How large was the lesion?

DR MALLORY The actual tumor was 1.5 cm. in diameter — not very large.

## CASE 34432

## PRESENTATION OF CASE

*First admission* A thirteen-year-old schoolboy entered the hospital complaining of frequent bowel movements.

For about one year prior to admission he had experienced rather constant diarrhea, with up to seven evacuations daily, unassociated with pain or bleeding.

Physical examination was essentially negative.
